1. Re: Fiber Optics in Ham Radio??

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-01 00:00:00 UTC
From: Alan Matheson <hokianga@ihug.co.nz>
Message-ID: <84jnjfbfp1@news.ihug.co.nz>
Source record: 64454

I am using polymer fibre optic cables with a homebrew RS232/FO converter each end to control a TenTec RX320 receiver located about 20 metres from my PC. This has almost totally eliminated interference from the PC used to control the radio. This wasn't a cheap option but there is a 20-25 db decrease in noise at frequencies in the 80 and 40 metre bands so it was well worth doing. I also plan to use a kitset audio F/O link to bring audio back to the computer soundcard for further processing. The kitset is much cheaper than the components required to build an interface.

Talk to survey equipment manufacturers such Leitz. They have complete
differential ground station solutions. You won't have to build anything.
Just turn it on!

>wiring
>princables?i have an spdt relay that has pinout like this:

Sorry, your diagram doesn't signify much. The various fonts and readers make a mess of most drawings.

Here's how I learned to work with relays.

Relays consist of two parts - the coil or coils, and one or more contacts. Energize the coil with the right voltage, and the contacts move.

The type of relays used in almost ham gear are "neutral" relays. This means that they have only two positions: "up" or energized, and "down", or deenergized. Polarity of energy to the coil makes no difference.

There are lots of other types, but we'll just discuss neutral relays here.

Each contact on a neutral relay have up to three parts:

the "heel", which is the part that moves,
the "front", which is the part that the heel touches when the relay is "up"
the "back", which is the part that the heel touches when the relay is "down"

For example, suppose you want to use a relay to switch a coax feedline between a transmitter and a receiver, and the relay is to be "up" (energized) when transmitting. A relay with one contact that has all three parts is needed. The coax feedline is connected to the "heel", the receiver is connected to the "back", and the transmitter is connected to the "front".

29. Free HP8551B/851B in Seattle area

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-02 00:00:00 UTC
From: John Miles <jmiles@pop.removethistomailme.net>
Message-ID: <386EC892.8CA@pop.removethistomailme.net>
Source record: 64482

It works great, but could probably use some new p/s filter caps and a weekend's worth of calibration.

Its CRT, BWO, mixer, and attenuator are good as new.

It is in very clean cosmetic condition, with a full set of manuals.

It weighs over 100 pounds, and is about half solid-state and half vacuum tube-based.

It consumes an entirely-unreasonable amount of electricity and bench space.

It will not be shipped anywhere, under any circumstances. You have to come and get it.

Send email explaining what it is, what you plan to do with it, and when you can come by and pick it up in Kirkland, WA.

Winner to be announced on Friday Jan 7. (Due to volume of mail received when I've offered things like this before, only the winner will receive a reply.) 73 es good luck!

Trying to identify. I have 3 of these and the only info on them that
appears meaningful is:

Model # FuF1848A
On the rx(?) circuit board 84D80949T01
On the tx(?) circuit board 84D80199M01
On the Eprom FRN4008A, V1.0 Mod B7

The front panel has a 2 digit channel LED
It has indicator lights (Tx/Bsy, Call, Scan)
It has pushbuttons (System, Subfleet, Phone, Scan, Select)

The front panel is labeled: MaxTrac 800

Barcoded on the chassis side is: HUF3037A.

The unit was made in Israel.

Can anyone give me technical info on the unit? It has got to be good for
something, right????

Greetings,

I'm about to begin building my first HF amplifier. By the time it's complete I should have a license class that grants the ability to use the thing. (still waiting on a callsign from a test I took over 2 weeks ago)

I'm going to start with either 813s or 4-400s (I have several of each). I've seen amplifiers in both grid-driven and cathode-driven configurations. I realize that cathode driven amps are easier to build and tune but also realize that the drive requirements of a grid-driven amp are much less.

I'm interested in the opinions of those with much more experience in this area and extend my sincere gratitude for the thoughts and opinions to those who respond.

Finding low powered exciters is somewhat of a problem.
Almost all transceivers are of the 100 watt range. For a
grid driven amplifier probably 5 watts or so is about right.
Grid driven amplifiers require rather substantion bias
supplies. I think the point to ponder for a while is why
no commercial manufacturer makes anything but the zero bias
grounded grid type, and this has been the case for about 30
years. I suggest some reading in Bill Orr's Radio Handbook.

Thanks for your thoughts. I have only a few schematics using 813s and I
think all of them are grid driven. I have some using the popular 3CXxxx
and 4CXxxx tubes but I understand these tubes are pretty grid-touchy and
I don't really want to start out with a tube like that. Maybe after a
few years of experience.... ;-)

Please send me anything that you can without going to too much trouble.
I'd be most grateful indeed!

Thanks again

Randall;
Just one opinion here but over 40 years of experience. A pair of 813's make a nice little kw amp. There are many parts, articles, and advice available cheap. I would not advise going directly to multi-grid tubes in a grid driven amp unless you have alot of experience. Hence, do yourself a big favor and make the 813 as a grounded grid--ie cathode driven animal. By the way, a pair of 813's above 15 meters start to be a little touchy because of the high inter-electrode capacitance.
If you need schematics for same, I have several and there some in the older ARRL Handbooks and the older ARRL SSB Handbook. I would be glad to send you copies if you do not have access to the books mentioned. Hard to beat a cheap ole 2X813 amp. 73 Bill (k6EC)

Check out http://www.downeastmicrowave.com and http://www.shfmicro.com.

Both are excellent sources of various GaAsFET's. I've always been hesitant to use devices from C-band LNA's as they could be damaged in the process, plus I often don't know what the devices are and don't have spec sheets.

Steve at Down East Microwave always includes the manufacturer's spec sheets at no charge with devices he sells - a very nice little "extra" to his customers.

It seems to me like early morning, approx. 0700 UTC, saturday and sundays
is your best chance. Check the signal of DCF39 (center freq 139.0kHz,
ASCII 200 baud, 340 Hz shift) to get an indication of band condition.
Measurements I've seen, seems to indicate that the strongest
amateur stations (at the same distance) might be some 40dB
weaker than DCF39 (maybe more).

Still haven't heard a thing up in JP53 :-(

Chuck Calloway dixit :

> Im wanting to build a 6 meter preamp & need a GaAsfet.Does any one know
> what equipment would have one like TV,VCR,Sat receiver?

Building a 6 m preamp with a GaAsFET is a waste of material. Not only it is almost impossible to correctly match a GaAsFET for Gamma Opt at low frequency (and there is no GaAsFET I know for which you will find s or noise parameters at 50 MHz), but you have also to face the flicker noise of these devices, which can be significant up to 100 MHz, with the consequencies that a simple FET like the J 310 can be much less noisy at 50 MHz than a PHEMT. As we say here in French : ï¿½ The best can be the ennemy of the good ï¿½.

So, just pick up a $.50 part at your local store and enjoy !

Hello,

I am looking for a CW QRP transceiver KIT. It should be sensitive, have about 4 to 5W output, easy to build and tune and have vfo covering the CW band. Of course price is also a item of interest.

My questions:
What rig should I chose ?
Wich band (30m or 20m) to have better results?
Should I go for a ready-to-go such as MFJ QRP CW Transeiver?

Thank you for your help

Luis Pacheco

48. Heathkit HW-101 60Hz noise

HI Group!

I was checking out my HW-101 over the holidays and I have noticed some odd things.

I was loading up the xmtr using an indoor antenna and a tuner. I had a receiver located in another part of the house. When I keyed the mic, I heard my voice in the other room, but it was
full of 60 Hz noises.

I am using a 50K Yaesu microphone that I wired to the 4 pin connector. My voice is readable.

Since the rig is older than my oldest child, I wonder if the power supply filter caps are dying.
Any replacement parts out there?

Anyone have a similar experience, but found it not to be the PS??

Yup, you sure did Jonesy... You are the first idiot to post.
You win the grand prize of being labeled as such.
Paul has the same questions I did early in my electronic journey, and asking such questions is not stupid. How many questions did you yourself ask when you got started? Did the person who answered them think they were stupid questions? Or, by some miraculous turn of events, were you born with all of the understanding of electronics it takes the rest of us years to learn?
Just because you think that Pauls questions are stupid or ignorant does not give you the right to flame him as you did, it was unfair and unjust of you to do so. If the people I had asked questions of while I was learning were as mean as you, then I would not be where I am today.
The only stupid question is the question that goes unasked.

Well maybe not a similar experience, but I've replaces many power supply filter caps in old AM receivers that caused the same problem in the audio.

I found it very difficult to replace the old 4 or 3-in-one caps with original type replacements (in some cases, very expensive). In most cases I just hooked up several caps of the stated capacitance is the identical way or made up strange value caps by combining modern caps(parallel or series)... worked fine on most rigs, but I did notice on some that PLACEMENT of the caps and lead length can also be a factor doing it this way.

Has anyone had a problem with RF getting into a weather station using a wind speed and direction indicator.
The main problem is in the wind speed indicator, being ofcourse a meter to measure voltage, bouncing up during key down on CW.
Any change to the internal circuit will put the wind speed out of calibration and I was wondering if anyone has had any luck with ferrite beads at the input leads.If so what number "mix" of beads are used. I tried several ferrite approaches by wrapping several turns around a ferrite stick, non of which worked . Jim

I refer you to John's answer above.

Somebody also better tell Icom that.

Geoff, Icom UK's service engineer uses one of their switchers as his
bench PSU.

Undetectable noise when sitting next to ANY receiver or transceiver to
date and has yet to fail.

Phil G4ZOW

Hi, Luis,

Are you an ARRL member? There is a table of QRP kits in the Members Only section of http://www.arrl.org compiled by Bruce Muscolino, W6TOY/3, with specs, prices and web sites of about ten different kit manufacturers. It may help you come to a decision.

R,

Al W6LX

64. Re: Ramsey Raid

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-03 00:00:00 UTC
From: sansimian <sansimian@home.com>
Message-ID: <2DDBB4788CA2C8F6.CC48BDAB95709A85.5B6A65B7992A8B7B@lp.airnews.net>
Source record: 64517

In the RS 2000 catalog... page 219, lower right corner, item # 28-4030, is functionaly identical to the kits sold by Ramsey. Therefore, if the kits sold by Ramsey are illegal, why not the kits from Radio Shack???

IMHO, the US customs is way off course here.

While I was in the millitary, I was in communications and cryptography, I have seen a LOT of other devices much more capable, have longer range, ect than either the kits sold by either Ramsey OR Radio Shack. The simple transmitters sold by both have very limited range. To be useful, they would need power amplification. and if an organisation had the person or persons capable of building the power amplifier, then the same persons would be capable of building the initial transmitter.
This kit sold by RS as well does not comply with the Federal Regs if built by a hobbyist. Read the regs... Also, the question of weather or not the kits, when assembled, comply with the regs is also a non issue.
And the commercial applications, such as they might be are not the issue.

The issue is that the US Customs officials raided a US bussiness for the alleged sales of devices to persons unknown for the purpose of aiding unnamed illegal activities.

If there was a person or organisation who decided to use the devices in question for illegal purposes, would it not be prudent to arrest them and prevent the illegal activities, rather than abuse and harrass the source of the items, a legitimate bussiness?
Say for instance, a guy goes into a Wal Mart, buys a ski mask, goes to the bank down the road, puts the ski mask on, and robs the bank. Is that Wal-mart's fault? Would the clerk or manager on duty need to worry about the FBI coming in and arresting them for the sale of the ski mask to a bank robber for the purposes of conceling his identity, then force Wal-Mart as a whole to discontinue the sale of ski masks? I dont think so...
Just remember the McDonalds hullaboo... Somebody spills coffee in their lap, sues the restraunt for their accident. McDonalds, had to pay... because the product they sold was misused by the person, causing the person a (hate to say this cause I dont believe it is true) injury. It wasnt that the employees of McDonalds spilled the coffee on the customer, but the customer spilling the coffee on herself. Common sense would tell you that COFFEE IS HOT!!! DUH!!!
So, why should Ramsey be held accountable for actions of a very few customers who may have engaged in illegal activities using the products sold by Ramsey?
The whole thing is ridiculous.

67. Low cost 80/40/20m CW QRP transceivers [SM6DJH]

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-03 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <3871229d.193022721@news.online.no>
Source record: 64520

In SM-QTC nr 12/99 and possibly nr 1/00 SM6DJH describes a rather
interesting high performance single band CW transceiver with ladder
type 5MHz xtal filter.
He underline the importance of using readily available components, the
transistor types have been available for almost 40 years and may still
be available in one or another version for many years to come, such it
is not possible to say about integrated circuits.
Semiconductors are BF199, BD135 (or BD137, BD139), BC547B (TUN) BF245B
and BC557B (TUP). The receiver even has AGC, some of it is on another
IF =1MHz using a 6MHz ceramic element in the oscillator. Only few
coils in RX and TX must be wound, in large extent is used fixed value
coils with values like 0�33, 1�H, 2�2, 10�H etc, it is therefore
easier to tune it up without too much complications.

RF output is 5W on 80m, 4W on 40m and 1.7 on 20m but using BFW16A or
2N4427 as driver stage the output may be increased to 3.2W

no email address is mentioned, only phone number

Question.....

If a rig wants to see 50 ohms and the ladder line is 450 ohms then why do you use a 4:1 balun??????

I am feeding a multiband dipole and using a tuner I don't really have any problems (except I can't load up on 160m).... My theory in antenna work is not the best and I am trying to learn as much as possible.

Thank You in Advance

Stephen

I was wondering the same thing. I'm still trying to figure out whether the original poster is looking for FM or CW/SSB capabilities.

It often seems like QRP is used to mean simple equipment. And when you see the term applied to VHF equipment, where low power seems more common than high power, the term doesn't quite make sense. By the time you have a receiver and a signal in one of the VHF bands, not only is it fairly complicated, but going to higher power doesn't add all that much complication.

You can have bare-bones VHF equipment, but to be just fairly capable it's going to be more complicated than bare-bones HF equipment.

Shielding, bypassing, inductive decoupling, more shielding, and then,
after all that, some more shielding, decoupling, and bypassing.

Wes Hayward has some good notes on shielding principles on his site at
http://www.teleport.com/~w7zoi/satutor.html. He talks about it in the
context of providing good isolation between modules in a homebrew
spectrum analyzer, but everything he points out is equally valid in the
switching-supply business.

I have a Heath HW-101 with a burned out choke in the plate circuit of the final amplifier. The diagram rates it at 425 microhenries.

Does anyone have something that would work in this spot? The old part mounts with #6 threaded holes in the ends of the ceramic form and is about 2.5 inches long and a half inch in diameter. Of course I am willing to try to fit in something else. Wire size has to be enough to handle around a quarter of an Ampere direct current I estimate.

If I can't find this part I may have to rewind the old one.

It sounds like an earth leakage detector (or safety switch) would
be a good investment at your QTH! They detect current in the earth
wiring and if any is detected, they trip and disconnect the active wire.
This assumes that the metal case of your rotator controller is earthed
(3 pin mains connector).

81. Coupled microstrip formulae ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-04 00:00:00 UTC
From: Vincent <vincent.habchi@art.alcatel.fr>
Message-ID: <3871D125.4347B52F@art.alcatel.fr>
Source record: 64394

Hi again,

has anybody out here formulae for computing even and odd mode impedances of coupled microstrip lines in the general case ?

The PUFF software I intended to use is a bit limited, in the sense that it can design only equal width strips, whereas for an interdigital filter I need to vary the widths and spacings.

Thanks
Vince, F5RCS

> you use a 4:1 balun??????

You have not said what is on the other end of the ladder line!
(Impedance wise.)

The transmission line only reflects the load to the transmitter.

In an ideal system (And there are FEW!) the antenna impedance would be 450
ohms,
the line would then be matched by a 9:1 balun to 50 ohms.
But, the antenna is probably NOT 450 ohms over the whole band or even not at
all.

> I am feeding a multiband dipole and using a tuner I don't really have any
> problems (except I can't load up on 160m).... My theory in antenna work
> is not the best and I am trying to learn as much as possible.

You see, the dipole is presenting the 450 ohm line with about 75 ohms.
(Gross oversimplification...)
and because you have not said what length (wavelengths) the transmission line
is
it could be a LOT of different impedances at the transmitter end.

Hello Everyone,

I have a Lowe HF-225 with options fitted as below and would like
to swap with a good portable or mobile dual bander. Or even an
older HF rig please.

D-225 FM detector/ AM sync board.
W-225 Antenna pre-amp and telescopic whip antenna.
K-225 Remote data entry keypad.
B-225 Internal NiCad battery pack.

Complete with power supply and handbook, all in mint condition.

Please reply direct to john@mm1dsp.freeserve.co.uk

Many thanks and a happy new year to everyone.
Regards,
John.

84. HP606B signal generator disaster

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-04 00:00:00 UTC
From: "Peter E. Orban" <Peter.Orban@nrc.ca>
Message-ID: <3871F25E.7924B148@nrc.ca>
Source record: 64397
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.equipment

Happy New Year to everyone!

One of the bands on my HP606B signal generator quit. Upon disassembly I found that one of the a coils on the amplifier turret assembly came loose, it got maimed, shorted, and eventually burned. It is the H coil, for the 1.76MHz - 6MHz band. The short question is, does anyone have a replacement coil by chance?

Interestingly, the generator was still working, except the output level could not be increased, and the signal was a bit distorted. That was when I took it apart. The above coil was a mess, but I could still count the turns. The circuit is a push-pull circuit, from the oscillator to the endstage, and the coil is part of the tuned plate tank circuit of the final amplifier. The coil assembly is fully symetrical, it had the secondary, the level control and output windings in the middle, and the main winding split, on both sides, wound in the zig-zag manner. The coil also has two slugs. First I rewound the coil as a one layer bifilar winding for the tuned part of the coil. I put it on a Q-meter, it was a reasonable coil, except I calculated it had about 70pF self capacitance (it needs to have less than 20pF or so, calculating from the circuit diagram). The coil I made was 2 x 24 turns, about 15mm in length, on the about 10mm diameter ceramic carrier, from 0.25mm enameled wire. Next I rewound it as two simple windings next to each other. It still has about 40pF self capacitance. I will make another try, with spacing between the turns. Interestingly, the oscillator coil for the same band is a one layer winding, and it uses a similar variable cap for tuning. The difference is that the ceramic form is about 20mm in diameter. If this does not work, then I guess I would have to find my misplaced zig-zag winding machine, or make another machine :-(
There is a resistor on the secondary winding that loads the coil, that also got burned a bit. It measured now about 700 Ohm. The manual gives a starting value of 100 Ohm, with a note that it is to be adjusted as required. I have some ideas, but unfortunately there are no notes in the manual on how to select the value.
Anyone by chance intimately familiar with this generator?

Thanks for your help, Peter

Hi Will, actually its on 14 mhz. As for the voltage that drives the wind speed indicator, its an AC voltage. The problem is nothing more than RF saturation as the wind speed indicators are mounted on the tower and the leads do run in along with the coax and rotor cables. These problems are some times difficult to solve and relocation of the weather station devices are often the solution. Through the years I have solved countless RF problems, non of which has ever required using ferrite beads. Jim

I would recommend the Wilderness Sierra QRP CW transceiver. I built it last year and it is terrific. Great fun to build, good instructions, easy to tune up. You have many options available and plug-in band modules for every band. You can buy just one and keep your costs down. The transceiver is very sensitive, great receiver, incredibly good break-in CW, very light and best of all it only consumes 35mA on receive. About 2.0-3.5 watts output, depending on input voltage and the way you wind the toroids. There is a digital readout, memory keyer and digital wattmeter module option that makes it a very high tech QRP rig!

really won't matter what band you use as far as clarity goes,
just get 2 'repeaters' on 900mHz.
1 with regular split and the other with an upside down split.
put 1 on each controller at each site and setup the controller to use
the box as a link port.
this assumes that the controller is capable of doing this.
i'm a little spoiled. i have an ff-800 controller.
plenty of rx/tx ports and config space.

Source record: 64406

You can get quite a bit more attenuation from a ferrite toroid than from a rod, because of the lack of a big air gap in the magnetic path. You'll get the most attenuation at 14 MHz from 70-series ferrites (using Fair/Rite-Amidon type designations), with a close second being type 43. Other high-permeability, low-frequency ferrites like Magnetics type J are fine also. All these maintain their impedance well into the VHF range. I'd wrap each cord going into the weather station, including the mains power cord, through a toroid core of one of these materials, using about ten turns, close to the weather station. You may also have to do some bypassing, but most of the energy will be common-mode, which the ferrite cores will greatly reduce.

If there are any electronic devices such as diodes at the sensor end of the line, you may have to give that end the same treatment. Otherwise, RF can be rectified by the devices and sent down to your weather station as ordinary DC along the normal signal path.

The impedance of the ferrite types I mentioned increases more-or-less linearly up to a few MHz, above which the attenuation is fairly constant with frequency for at least a couple of decades.

Roy Lewallen, W7EL

Depending on what frequency the interfereing RF is, the ferrite may not work very well. At higher frequencies, above a few hundred MHz, the ferrite beads start to lose it's attenuation. You may have to put in a low-pass filter near the meter. I'm assuming the speed indicator voltage is DC or near it. Maybe a series of capacitors shunted to ground will help?

Just thinking out loud...

Will

Charles Reichert scripsit :

> Actually it is easy to design low noise optimized 6 Meter Preamps
> using GaAsFETs. I've built many from HF thru 432.
> Try out my free Preamp Design Program (ASP 4.0) available at
> http://www.mbn.net/kd9jq/hamradio

Great, I will ! Thank you for giving away for free these kinds of very valuable software.

Yet, the 3SK... part you seem to use sounds is a dual-gate (GaAs) FET. In this case, you are right, those devices are low-noise from HF to VHF (I know about the very classical european CF 300). But they can't be used beyond 1 GHz, which is precisely where the ï¿½ true ï¿½ GaAsFET (three ports) takes over.

Devices like ATF21186, MGF1302, ATF35086, ATF13056, etc. are not suitable for use under 500 MHz.
Anyway, 500 MHz is already BF... try an op-amp !)))

Cheers,
Vincent

Hello,

I recently added a PREFIX look-up form on the QSL page. If you need to know where a prefix is from, simply enter the call or prefix and see what country it is assigned to.

You are invited to http://hfradio.org, a non-commercial site offering:

+ Azimuth Map / Equidistant Map Creation (choose any QTH as center, many options)

+ Propagational Resources (live, real-time reports, eAlert service (sign up for automatic email solar/geo reports, complete with Aurora index))

+ News, and DX information and reports

+ QSL Manager and Callsign Lookup center

+ Swap and Shop

+ FREE HOME PAGES THAT YOU CAN USE TO POST YOUR OWN HAM OR SWL SITE

+ Bookstore - SWL and Ham related books. Over a 1000 titles so far.

+ Plus more (Directories, etc.)

73!

109. Help - What is S-9 Voltage??

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-05 00:00:00 UTC
From: VE6INM <ve6inm@telusplanet.net>
Message-ID: <84voktlr1@nnrp1.deja.com>
Source record: 64412

One of my current projects is the restoration of an old Trio/Kenwood TS-600 radio. While going through the rig and restoring everything to the factory specs, I have across a bit of a problem. While setting up the S-meter sensitivity, the service manual states that the S-1 level is referenced to 0.5mV from the sig gen and S-9 is referenced at 50.0mv. Making the assumption that this is a misprint and both voltages should be microvolts not millivolts, is there an "accepted standard" for what an S-9 reading really represents. All of my old books and service manuals are wishy washy concering this, stating that the reading is all relative. About the best I could find from a "reliable" source, was an article by Art Collins from back in the early fifties. He suggested that 50.0uV of antenna input voltage should be referenced as S-9 and each downward S-unit be 6dB down from that. If there is not an accepted standard, what the heck am I doing reporting signal strength back to another station when I really don't know what that strength is? Or is this tired old brain just missing something real simple. Any help or insight would be greatly appreciated.
Best wishes for Year 2000.

Message-ID: <t7Lc4.6413$475.150175@news4.giganews.com>
Source record: 64418

Originally S units were estimated by ear, with S9 being 'extremely strong' and S1 being 'extremely weak.' Then someone invented the S meter.

For a while there was some variation in standards, with S9 being either 50 or 100 microvolts and an S unit being 6 dB or so, sometimes 5 dB.

Currently it seems standard for S9 to be 50 microvolts and 6 dB per S unit. That is, in a 50 Ohm system.

Message-ID: <38738D18.729BFDA0@eznec.com>
Source record: 64419

Some receivers seem to be adjusted to 50 uV for S-9, but very few if any are 6 dB per S unit. Most are less, and many are much less. Most vary considerably over the scale. My Icom 730, for example, varies from 1.4 to 4.0 dB per S unit over the scale. "10 dB" increments over S-9 vary from 5.6 to 13.5.

If you assume your S meter is showing 6 dB per S unit, you can come to some very wrong conclusions. I frequently give a talk on antenna fundamentals, and one of several claims I make at the beginning is that I'll tell how to make a 3-element beam with 3 S-units of gain compared to a dipole. No problem. On my Icom, S-2 to S-5 is 5.2 dB, a cinch for 3 elements.

What is S-9 Voltage? How long is a piece of string?

I can't remember where, but I have read that S9 = 50 microVolts
and one S unit = 6dB. There is lots of debate about this. Some
people regard S9 as 30 microvolts and one S unit as 3dB.

This raises another question. Is it 50 microVolts peak,
peak to peak, or RMS?

Who says "no commercial manufacturer makes anything but zero bias gorunded grid type" amplifiers? One I can name among others is QRO. Sorry Ross but your
wrong! But I do agree that for a first time project the zero bias, grounded grid amplifier would be much easier to do.

I do like my easy to tune, low power drive, grid driven QRO HF-2500DX.

the parameters are thus,

50 ohm load, 600vpp, or 300vp, on a 'two tone' steady state
signal. The amp (a single 8930) delivers over 200 watts cw, and
seems to deliver 100 watts of carrier with enough head room to
forward modulate 100% (i am assuming 400 watts or approximately
200vp) as i easily see this much on my scope. So, what is the PEP
with 300vp showing on my scope?

Hi, Glenn,

The difference between S9 and S1 is 8 S units. By Kenwood's own numbers, 0.5 uV and 50 uV, that's a difference of 40 dB. That means each Kenwood S unit is 5 dB.

Of course, they had to spec S1 at some level, and they chose what is probably the sensitivity of the receiver, 0.5 uV. Otherwise the noise floor is reached somewhere between S3 and S2, but nobody would want their S meter sitting at S3 after disconnecting the antenna.

All this goes to show the utter failure of the S unit reporting system as anything other than an interesting number to give the other guy. A calibrated voltmeter would be way better, but way expensive. Actually, I take that back. It may not be too expensive if the RF gain, mixer loss, and IF AGC transfer function were well-known. Uh, I guess it would be expensive after all.

The general consensus seems to be that S-9 is 50 uV. When you get around to calibrating the receiver, depending on the signal generator you are using, you will either set the level control on the sig gen to read 50 uV or 100 uV to actually get 50 uV at the input of the TS-600.

This is because some sig gens read "open circuit terminal voltage". When you connect the 50 ohm sig gen output to the 50 ohm input of the receiver, the voltage divider formed by those two will split the available output signal, and half of the "open circuit terminal voltage" will appear at the antenna connector of your radio. On these sig gens, setting the dial to "100 uV" means 50 uV at the input of the receiver. Weird, huh?

R,

Al W6LX

Well Gentlemen,
As usual, the mud is much clearer now. Thank you all for the information and insight. It would appear that Art Collins was pretty much bang on (but that doesn't surprise me). As Roy stated and I must agree, the S-meter linearity on this rcvr or any of my others is just not there, so the 6dB per unit will be pretty difficult to interpret. All of you seem to agree that, at least at some point in the past, 50uV was used to set an S-9 point...whew, at least I had that much right. Al brought up an interesting point about the sig gen voltage as did Eamon. Is this peak, P-P, RMS or what? I am assuming P-P but could be grossly wrong there. Combining all these NEW un-answered questions with this old brain just about overwhelms me. Maybe I'll think like Eamon - "How long is a piece of string", and act like Bob - disconnect the damn meter and use my ears as the gauge!! After all it worked for me 30 years ago, why wouldn't it work now.

Seriously guys, my truly sincere thanx for the input. It is appreciated and certainly will not be wasted. Now I think I'm gonna go build me one of them beams that Roy designs. With the 6dB gain on 3 elements.
Cheers,

>S unit is 5 dB.

No it doesn't - in almost all commercial transceivers the "value" of the S-unit varies with signal level.

The S-meter *scale* is usually drawn linear, but the linearity of the S-meter *response* depends on how the IF gain changes in response to voltage on the AGC line. In practice this change is only approximately logarithmic, so the S-meter response is non-linear.

According to the detailed equipment reviews in RadCom and QST, the difference between S9 and S9+20dB is usually pretty accurate in modern transceivers, but the value of a single S-point tends to vary between maybe only 2-3dB around S1-2, up to more like 6dB between S8 and S9.

The signal level for S9 varies from maker to maker, model to model, and rig to rig.

I enjoyed your other responses. I have found that, with typical imported VHF radios such as 2 meter FM units, ONE dB per S-unit is much closer to reality. As noted, it varies, and the perceived audio S-unit reports are probably more accurate so far as signal reporting goes.
Someone can be "S-9" on the S-meter but barely readable through the noise. Another station can be loud and clear, for instance on 10 meters, but is not moving the S meter at all. If you tell the other station he's not moving the S meter, he will invariably be disappointed, so many of us "pad" the report to puff up the other guy. The audio report of loud and clear is much more definitive.
Then, of course, there's the "Contest" version of S-meter or signal reports: "YOUR REPORT IS 5-9, OM, PSE RPT UR CALL, QRZ?"
Jim W5AOX

141. Need info on Kenwood TS570SG!

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <20000106103604.19673.00000047@ng-fl1.aol.com>
Source record: 64355

Hi,

I need the MARS/CAP mod for the TS570SG in order to be able to drive my Ten Tec 2 meter transverter to cover the entire 2 meter band. The rig has to transmit 28.000 - 32.000MHz to do cover it. Kenwood will not release the info. Without opening up the radio I only have 144-145.700 2 meter coverage. NOTE: I have seen the mod listed on QRZ and another site for the TS570D and DG models and they are completely diferent mods, so this needs to be specific to the TS570SG model.

Thanks!

You can expect around one millivolt from a high impedance microphone and correspondingly less from low impedance. Maybe a bit more but it's nice to have some reserve gain.

Check the specifications on the particular microphone you want to use. It will be rated, often, in dB with respect to one millibar or something like that. Of course you should know how sensitive you want it to be; if you close talk a microphone you will get higher output and if you want pickup from across the room you won't get much. You can't overload a microphone by yelling into it, as a general rule.

Source record: 64359

I think the PEP is the rms of the peak of the rf envelope. In other words, it's not the peak power at all, just the rms you have at the peak moment of the modulation.

So looking at the oscilloscope, take the absolute peak voltage you see with maximum modulation, and find its rms equivalent for that cycle. For instance, a 200 Volt peak would imply an rms of 141.4 Volts. Into 50 Ohms that would be 400 Watts pep if my mental calculation is correct.

Find a 2M 5/8 antenna that shows an open from center pin to ground (this ensures it does not use a tapped coil for matching). It will tune up as a 1/4 wave on 6M.

Yow. I've never heard of that.

As far as I'm aware, the output of any calibrated signal generator with
an N or BNC connector is rated assuming a 50-ohm resistive load.

Any signal generator not matching the above description should not be
used for anything but spare parts.

156. A to D For Rotator Indicator?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-06 00:00:00 UTC
From: Lee Smith <ckvnfm@mb.sympatico.ca>
Message-ID: <A6ed4.715$k6.15237@news1.mts.net>
Source record: 64370

Hello Folks:

My Ham IV rotator is developing problems with the wiper arm of the position feedback pot. Right now, on a good day, it might work 10% of the time. This means that in the spring I will have to pull the rotator and do a replacement.

In the last while, I have seen a few good pictures from OLD magazines of stations with a large great circle map on the wall with the beam indicator built in via a selsyn system.

That got me wondering about the method to build a similar indication system based on a stepper motor and an A to D converter. Maybe a back-lit mask that would illuminate the beam pattern onto the map would be another thing on the wishlist.

Does anyone have any circuits out there for this sort of thing already? Or maybe you could recommend a way to go about it.

I think it would make for a neat thing for the shack, as I am going to be doing a "to the walls" tearout of the radio room and it is a good opportunity to incorporate this idea.

73 folks.
Lee Smith

Does anyone have a 1.2GHz duplexer that would like to sell? I need a small input power tollerance (up to 20W max!), separation of 80-90dB @ 40 MHz spacing and the insertion loss as minimum as possible... Doesn't have to be new, a used one is just as good. The price is the key factor.

YZ7REA Vladimir

Dear List:

I'm looking for a way to emit a 2.1-2.2GHz transmitter to test a RF receiver operating at that freq. range. Please suggest any ideas you have. I have the following for now:

1) Build a lambda/4 < 4 cm monopole hooked up to a function generator.

Problem:
There's no function generators operating at 2.1-2.2GHz so I must somehow get a resonator. Can I use a resonator to drive teh monopole directly?

Thanks
Titus

>forward modulate 100% (i am assuming 400 watts or approximately
>200vp) as i easily see this much on my scope. So, what is the PEP
>with 300vp showing on my scope?
>

PEP = power during an integral number of full cycles at the peak of the RF envelope... = (Vrms[of those cycles])^2/Rload = (Vpeak)^2/(2*Rload). Assuming the peak voltage is 300 volts and nominally sinusoidal and the load is really 50 ohms, it's 300^2/(2*50) = 900 watts. The RMS voltage is about 300/sqrt(2).

Cheers,
Tom

Hi John,

I am certainly interested in those articles. My plans are to build the RX on two separate chassis, one for power supply and audio stages and the other for the detector and possibly an RF-amp. So I would be able to try different kinds of detectors. Most parts needed are here already. A problem is to get the plug-in coil forms, so I will have to make them myself from PVC tubing and octal plugs. If you could mail the articles mentioned to me it would be very kind.

Best regards and mni 73s

need a 12dB amplifier, possibly high IP and a divide by 4 hybrid,
consisting of 5 equal resistors, value 30 ohm, 33 ohm will work well

The amplifier may use a 2N3866 or BFR96. Have a circuit for 14dB
broadband amplifier (1-30MHz) with 2N3866 just tested, also tested a
BFR96 amplifier, this has 15dB gain, was found in QST, but such
circuits are shown in W7ZOI/W1FB's book "Solid state design manual"

my circuits are available as gif files. With 0.1uF capacitors they
will work down below 200kHz, I modified them for use as pre-amps for
136/1800kHz receiption, with 0/10/20dB attenuator

The problem using 50 ohm amplifier with the simple divider is that
unused outputs must be terminated (47 ohm resistor).

> 73, Bob K6DDX
>
>

We must be careful with the words. RMS is applied to voltages and currents, not to powers. As it is a mathematical calculation, obviously a RMS power can be calculated but it has no useful meaning.
When we have a DC on a resistor R, the power (time constant) is V²/R or I².R but when we are dealing with AC (or generally variable voltages/currents) we can see that the power is time dependent (not time constant any more) then we define 2 powers: the instant power and the average power. The former still is V²/r or I².R (with V and I the instant voltage and current). But the latter has to be calculated. As it is an average value, it it time constant. So, we can search for a DC value of the voltage/current that produces on that resistor the same power of the AC during a certain time (if the AC is periodic this time is the period). This constant voltage/current value is called the effective value of the variable voltage/current. But mathematically it is easily shown that this effective value is the RMS value of the voltage/current, that is, its root mean square value, a saure root of an time integral calculus.
So, the effective or RMS value of a variable voltage/current signal is the value of a DC signal that, applied to a resistor, produces the same power that the original variable one (it occurs that, for pure sinusoidal signals, the RMS is the peak value divided by sqrt(2)).
Thus, we talk about average power and NOT about RMS power.
PEP is a power calculated with the voltage/current peak value and is related to the average one. For fixing this relation, PEP is normally referred to a two tone steady state modulating signal.

Hi Carel
An other interesting article about Ladder filter is the following :

Designing and Building High Performance Crystal Ladder Filter by
J.Makhinson in QEX Jan 1995 pp : 3- 17.

The author uses the tools of Hayward (in Introduction to Radio Frequency
Design) to develop high performance filters (low ripple, high shape
factor,...)

I have used the Hayward and Makhinson papers to succesfully design
several ladder filters some years ago :
- 12 poles SSB filter (BW : 2.3kHz, IL : 2.5dB, S.F : 1.6)
- 6 poles CW filters (BW 360Hz, I.L : 10dB)
- 4 poles Noise filter (BW : 2.7kHz, I.L : 2.5dB)
All these filters are 50 ohms and the input of the SSB one is connected
to the post mixer amplifier via a 6dB attenuator in order to limit
impedance changes.
Good luck and 73's

>an N or BNC connector is rated assuming a 50-ohm resistive load.

>Any signal generator not matching the above description should not be
>used for anything but spare parts.

Remember to problem of specifying the sensitivity of BC FM receivers?
Some specified the input as the generator open circuit voltage into
300 ohms (balanced), other into 75 ohms (unbalanced). But since
specifying the actual antenna terminal voltage gives smaller numbers,
which look better in advertisements, more and more companies specified
the loaded generator voltage into either 300 or 75 ohms. I guess some
even specified it at 50 ohms to get a smaller number.

The standard finally adapted for BC receivers was to express the
required input _power_ for a specific SNR and specify the power in dBf
(decibels relative to a femtowatt or 1E-15 W). In this way it did not
matter what the impedance was and it also solved the open
circuit/loaded issue. The sensitivity for monophonic reception is
about 1E-14 W or 10 dBf or -140 dBW or -110 dBm.

Thus if S9 is 50 uVrms into 50 ohms, as usually defined for HF gear,
this is equivalent to -103 dBW, -73 dBm or +47dbf. With S9 at -73 dBm,
S0 would be (assuming 6dB/S unit) -127 dBm. For a NBFM receiver, the
usable sensitivity is about -120 dBm, while for VHF/UHF receivers
around -130 dBm.

But due to the higher background noise on MF/HF there is not much need
for SSB receiver sensitivities better than -110 .. -120 dBm, thus, a
calibrated S meter would show S3 .. S1 even without an antenna.

As a curiosity (and to add to the confusion), I have seen some claims that S9 for VHF/UHF equipment should be 5 uVrms, but I have not seen any formal definitions about this :-).

>A GFI in a hamshack would be a very good idea.

And get all kind of false triggering due to RFI...

While the GFI is a good idea when working inside a live device on the bench, however, the GFI it is not a substitution for an isolation transformer. Due to the RF sensitivity of the GFI, it might not be a good idea to take all the normal operating power through the GFI. With a separate grounding electrode for the antenna tower, you quickly end up in ground loop currents even without the presence of RF, which can trigger the GFI.

For safe operation, it is important that every chassis is securely connected to the protective ground and that all wires and connectors are selected based on the fuse rating (and preferably using even thicker wires) to insure that the fuse is blown quickly, if the live ever gets connected to the chassis.

List Of Stamp Applications (L.O.S.A for short)
==============================================

If you have done something (big or small) with the BASIC Stamp
that you are willing to tell others please use the form below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Then e-mail the form to:

cj@hth.com

With the following as the subject:

L.O.S.A Contribution

Or you could point your Web-browser to the following URL and fill
in the L.O.S.A form on the Web-page...

### OBSERVE! NEW URL - UPDATE YOUR LINKS AND BOOKMARKS ###

http://www.hth.com/losa/

The latest version of L.O.S.A is always available at the above
mentioned both in ASCII and in ZIP-file format for easy download.
An index of L.O.S.A is posted to the following mailing lists and
news groups, I will update it approx. once a month.

Mailing lists:

BASIC Stamp Mailing List

News groups:

comp.robotics.misc
comp.home.automation
sci.electronics
sci.electronics.misc
rec.radio.amateur.homebrew

FTP-site:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

You can also find the latest version on the following URL...

I do! I got my start much the same way as Paul...at 7 or 8 I was
tearing apart old TV's saving all those wierd little thingies and
later asking people what they were. Later my Dad had one of the early
30-in-one (that did NOT have a breadboard, only the spring things)
that I thought was the coolest thing in the world!

For Christmas this year I bought my 11 year old one of the 300-in-one
kits at Radio Shack, and I'm not sure which one of us enjoy it more! I
think these are an excellent tool to help you get started. Be advised
that the 300-in-one can be a little intimidating to the newbie, so you
might start with the smaller one.

> PEP is a power calculated with the voltage/current peak value and is
> related to the average one. For fixing this relation, PEP is
> normally referred to a two tone steady state modulating signal.

But we should be clear: the PEP is NOT the instantaneous peak power, but the average power over one complete RF cycle (or a small integral number of cycles) at the maximum of the time-varying signal. It can be the peak of some specific signal, or it can be the peak power the amplifier handles/is designed to handle.

For example, you might feed an amplifier rated at 200W PEP a two-tone test signal that hits 100W PEP. Into a 50 ohm load, on envelope peaks, the 100W PEP signal would have cycles that have an output RMS voltage of 70.71V, and a peak voltage of 100V. But the amplifier, rated at 200W PEP, is still capable of peaks of 100V RMS which is the same as 141.4V peak in the narrowband signal. And knowing the PEP really tells you nothing of the average RF power, unless you also know the envelope, since the signal could be CW, where the PEP is maintained all the time and is equal to average, or it could be from a very "peaky" impulsive voice waveform, and average far, far below the peak level. (It's good to know, for an amplifier, what average power it is rated for. That's not necessarily the same as the PEP rating, and depends on cooling and power supply capability in addition to the amplifier component instantaneous voltage and current ratings.)

Cheers,
Tom

I would think it would be more cost effective to build a simple
audio-oscillator to send via FM, and use existing FM equipment. I have
seen a couple of these, and they seem pretty simple.

Well, that's what I get for being helpful and looking up data in the Handbook for someone.
My 1944 ARRL handbook must be mistaken, as it plainly states 500 mA for the 12A6 at 12.6 volts...
However, I have conclusive proof of the current drain. Unlike you guys, I found a NIB 12A6 (RCA) and
applied 12.6 VDC to the filament (pins 2 and 7), and the MEASURED current drain is..... 153 mA.
So there.
Jim W5AOX

All prices plus shipping from 07657.

1.) Pair of Bogen MO-100 monoblocks. These are the early version that uses 6550's, rather than 8417's. With mounting rack. 100 watts/channel tube power amps. Sound great--recently rebuilt (3 months ago) with modern electrolytics and Svetlana 6550C tubes. $400 for the pair.

2.) Oregon Electronics vacuum tube regulated power supply. Model 5-3. 0-500 V @ 500 mA adjustable HV. 0-150 Bias. Dual 6.3 V/10A filament outputs. Volt/amp meters. A great testbench supply! Uses 4 Amperex 807 tubes as pass regulators. $150

4.) Good, used, tested Telefunken smooth plate ECC83/12AX7. Pulls from test equipment. $15 each

5.) Good, used, tested Amperex ECC88/6DJ8 "Bugle Boy". Pulls from test equipment. $15 each

6.) RCA 810 triode. JAN type CRC-810. Pull from unused equipment. $40 --With Johnson socket and Triad F-33U filament tranny $55

7.) Penta Labs PL-254W Triode. Pull from unused equipment. $25

8.) 2 pcs 4E27A/5-125B pentodes. 1 Eimac, 1 Sylvania. Both are NOS, but Eimac box is missing. $30 each or $50 for the pair.

9.) Westinghouse 5CX1500A pentode. Pull from working equipment. Tube tests good. $75

10.) RCA radiotron UV-201A Used, tests good. Brass base early triode. With bakelite "breadboard" socket. $30

11.)Modified Techron 8521 power amp in roll-around 19" EIA rack. Can deliver
over 5kW into a 2 ohm load. Frequency response DC-50kHz. +/-140V output.

Unit was a pull from an MRI scanner, and has been modified to operate from single phase 208-240 VAC power. All modifications professionally done. (Original xfmr, filters, rectifier removed, and replaced with fully rated single phase equivalents) Possible uses:

Motor driver
ELF transmitter
Shake/vibration testing
Stadium/Concert hall PA system
General scientific research

Or use it as the biggest subwoofer amp on the block! Just the thing to wake the neighbors early on xmas day! :)
Best offer over $750 takes it. Unit is located in Northern NJ, and will deliver within 50 mile radius, or you can pick it up. This thing is HEAVY, but will ship via truck if desired (at buyers expense for shipping and crating).

12.) General Radio (manufactured by Tektronix) X-Y display scope. Great for checking phase shift, plotting output of a curve tracer, or just hooking up to your system for the "trippy" lissajou display.:) Great condition--VERY bright CRT with no burns. $35

13.) HP 651A Audio Oscillator. 10Hz-10MHz sine wave. 19" Rack Mountable Good condition. $75

14.) Boonton Radio (HP) 202H RF generator 54-216 MHz AM/FM Rack Mount Good condition $50

15.) Tektronix R5103 oscilloscope. Mainframe is in good working condition. Accepts all 5000 series plugins. Comes with 5A16 dual trace amp and 5B10 timebase. Plugins need work. $25

16.) A bunch of NOS tubes. Mostly RCA, GE, Sylvania. Many industrial types.Want to sell them as a lot. $300 for the lot (189 pcs) Types and quantities as follows:

185. Re: Crystal Ladder Filter Design

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-07 00:00:00 UTC
From: Jim Pennell <no-spam@spam.com>
Message-ID: <856dngvhf1@nntp6.atl.mindspring.net>
Source record: 64388

The Hayward article is included in an ARRL book "QRP CLASSICS" and I believe it can still be ordered from ARRL.

I also see it is in the ARRL book "W1FB's DESIGN NOTEBOOK" and this is probably the better book to get, since it includes several other articles on crystal filter designs, and methods of measuring the crystals.

As for QEX, there is a CDROM which ARRL has wiht issues from 1981 to 1998.

I've built a ladder filter for 5.0000 MHz - CW bandwdth, and it was amazingly simple.

Good luck, Jim Pennell

Message-ID: <856o8deef1@nntp4.atl.mindspring.net>
Source record: 64295
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew,rec.radio.amateur.policy

Well, with the new R&O changes, I'm studying the question pools to get the CSCEs for my extra (I have 5wpm, and general theory already done as I have a pre 1987 tech). Think I know enough to pass, but I can't seem to calculate correctly "Q" given the frequency, inductance, and resistance of a circuit.

I *thought* the equasion for the reactance of an inductance is:

Xl = 2pi*f*L

and the equasion for Q:

Q = X/r

Combined:

Q = (2 pi *f*L)/r

Which yields wrong answers! :-(

What did I screw up?

188. Swept Frequency Generator

Hi groups,

After the article from Wes Hayward, W7ZOI about designing crystal ladder filters, I am now searching for a copy of an article from Randy Henserson WI5W titled: "A swept Frequency Generator" written in QEX March 1994. A brief version is in the ARRL Handbook 1995, chapter 16. I own this book but maybe the original article has additional information. I'm not a member of ARRL, so cannot order a copy there.

Can anyone pass me a copy?

73 Carel, PA0CMU.

Does anyone have a source / part number for the power connector plug for the FT8100R? This is a ham dual band mobile, but the power connector (a T type quick disconnect) is used by almost all the major brands for the VHF/UHF rigs.

It is possible to purchase additional power cables, for a large nominal fee, but would like to find a source for the connector only so that I would custom make what I need.

TNX in advance for the response.

In the UK I think it was RS or perhaps Maplins who used to do a wind
your own
mains transformer kit, in various power ratings. The primary is
pre-wound and
you just wrap round the requisite secondary turns. They give you data on
this. I built one and it still works. Predicted output e.m.f. not too
far
from the eventual result.

>How about Ten Tec? They have QRP Xcievers for 20, 30,40 & 80 meters....3
>watts out. See
>http://www.tentec.com for details. Price is $95 US.

I'm with Jim on this one... great performance for under $100... I
built my 40 meter version the weekend before field day 99 and then
gave it quite a workout during field day. With a 12 V, 7AH gel-cell,
it had about 3-3.5 watts out to a 40 meter portable inverted vee... I
made 170 contacts in 18 hours. Field day is a good test of receiver
dynamic range and selectivity, and the receiver in this one did a
great job!

Unless things have changed, you can get back issues of QST, or photocopies
of specific articles if the issue is no longer available, from the ARRL.
You'd have to pay for the issue, or the photocopying, but there never used
to be a restriction on who could take advantage of this.

This is why I don't quite understand the ARRL's policy of making the
cumulative index of QST on the web for members only' it is helpful
to everyone and could indeed help to sell back issues.

On the other hand, b eing in Canada I have a slight idea of what it's
like to deal across a border, in another currency, so hopefully in
this case you can find someone who has the article.

I've enver seent he article in question, but yes, I'm under the impression
that sometimes articles are shortened a bit when they are put into
the Handbook.

A simple solution would be to float a 7 ampHour 12 volt Gel Cell
of a 3 Amp 13.8 volt regulated supply. This could easily give you 20
or 50 amps for short(or long -10s of minutes) transmits while still being
small and cheap to build.

I plan to build something like this myself for the ten-tec 555

73s

hi ,

good job with the 12a6.

Now you can build a small Xtal transmitter for 80M band
and play with it.

Power Supply Transformer

Paeco model 4026. Dual primary winding for 115 or 230 volts. Secondary windings are as follows... 920 VCT at 100 mA, 5 V at 2 A, 5 V at 6 A, 6.3 V at 8 A, 6.3 V at 6 A, and 6.3 V at 6 A. All connections are via solder posts on a terminal strip. Mounting is via 4 bolts which are included. I checked all the windings with an ohm meter and they check out OK

208. FS: Stancor power transformers, NIB

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-09 00:00:00 UTC
From: ovrreactor@aol.com-nospam
Message-ID: <20000108202634.03570.00001060@ng-fx1.aol.com>
Source record: 64307

I am selling a few Stancor power transformers, new in box, part number P-8365. Primary is 117 V. Secondaries are;

570 VCT (285-0-285) at 325 Ma DC
5.0 V at 6 A
12.6 VCT at 6A

The HV secondary is WAY beefier than anything in the AES catalog. And that's 400 VDC on B+, if you use a full wave SS rectifier circuit, or 800 VDC if you use a full wave bridge and ignore the center tap. (Obviously, lower B+ if you use a tube rectifier.)

SO WHAT if there's the filament secondary is 12.6 V! Just use half of that secondary for 6.3 V, and use a pair of resistors to ground to get the CT. OR you can use some 12 V variant "budget" tubes. I guess you could even use the 5 V secondary to run some 6 V tubes (or 5 volt variants).

There's a lot of different options for this transformer...just use a little imagination.

Asking $45, plus shipping (9.5 pounds).

Interested? Please respond by email to < OvrReactor@aol.com >.

Best Regards,
Tom Mitchell

Paeco model 4026. Dual primary winding for 115 or 230 volts. Secondary windings are as follows... 920 VCT at 100 mA, 5 V at 2 A, 5 V at 6 A, 6.3 V at 8 A, 6.3 V at 6 A, and 6.3 V at 6 A. All connections are via solder posts on a terminal strip. Mounting is via 4 bolts which are included. I checked all the windings with an ohm meter and they check out OK.

This is a digital panel meter manufactured by Digitec. It measures DC voltage, and uses 4 miniature nixie tubes to display the reading. It is powered directly by 110 VAC, which is applied to the rear panel. The voltage to be measured is also applied to the rear panel. The two screwdriver adjustments on the front panel are for gain and offset. It works well...the third picture shows the reading from a 9V transistor battery.

225. question 74LS04 as xtal osc.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-09 00:00:00 UTC
From: hexter@blazenet.net
Message-ID: <XyUd4.11941$7L.487774@tw11.nn.bcandid.com>
Source record: 64324

i have a 74LS04 in the classic two gate oscillator circuit. i am using 560 ohm resistors (pin 1 to 2, and pin 3 to 4) to bias the gates into a semi linear area. pin 2 is connected to pin 3, and the crystal with a 12pf capacitor in series is connected from pin 4 back to pin to complete the ring oscillator.

Now here is the question, the xtal (a small hc/49 style) is supposed to be a third overtone cut, but it insists on running at the 9 mhz fundamental. anyone have any tricks to kick it, and keep it in the 10 meter band? i could build a tripler, but that would defeat the original design goal.

tnx 73

What did you pull it out of? An old DEC PDP-8, or PDP-11 mini? You mite want to post this on some of the electronics and computer equipment news groups. There are some people out there who collect old computers, and if the core memory boards you have work they maybe of great interest to somebody trying to restore one of these old machines.

>
> What did I screw up?

It makes a difference if the circuit in question is a parallel or series
circuit. The equations you used are correct for a series connection of a
resistor and an inductance. For a parallel connection the equation is
different.

For a parallel connection of X and R you get:

Z=1/[(1/R)+(1/X*i)] where i=sqrt(-1) and X=2*Pi*F*L

Z=[(R*X^2)/(X^2+R^2)]+i*[(R^2*X)/(X^2+R^2)]

Now the part multiplied by "i" is the equivalent inductive reactance (Xeq)
of the parallel circuit, and the remaining part is the equivalent resistive
(Req) part.

The Q is still calculated by X/R, but in the parallel case it is Xeq/Req,
which yields
R/X, for the paralleled inductive reactance and resistance.

You can also look up the above equation (#15) in the 1999 ARRL HB on page 13.5.

Good luck on your exam!

Gate oscillators don't make reliable 3rd overtone oscillators without some type of fundamental mode trap in the loop. You might be able to replace the 12 pf cap with a parallel resonant tank. The tank should be resonant slightly above 9 MHz (say 12 to 15 MHz) and have an equivalent "c" of 12 pf at 28 MHz. You may have to add a dc blocking cap in series with the tank, depending on your circuit.

232. Which Microwave Band?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-09 00:00:00 UTC
From: Brad Dyson <n4trc@prodigy.net>
Message-ID: <85a0r8$1340$1@newssvr04-int.news.prodigy.com>
Source record: 64331

I am considering which Microwave band that I want to start out experimentations with. Here is some of the criterion that I am considering:

-Kit availability

-# of operators in that band

-Flexibility of equipment- can I do other modes (FSTV, Spread spectrum, etc)

-how soon the FCC will give it up to commercial interests:
My impressions say that 902, 1.2Ghz, 2 Ghz, 3 Ghz, 5.7 Ghz will go to various commercial uses just as soon as the FCC 'discovers' that that RF safety loophole extends further than they originally planned (take a look at their figures NOW, it progresses almost linearly with frequency until it hits about 800 Mhz or so, and then 'magically' RF there becomes a little 'safer' for cell phones). We will have the opportunity to shower our heads with RF from phones operating as high as 3Ghz, I figure (any opinions on this are welcome).

I read not too long ago that certain bands between 2 and 10Ghz are already being considered for satellite-based continuous music programming pumped into cars, as well as more TV, phone use, etc. Which band might be the most immune to this trend, and why (propagation limitations, equipment availability, etc)?

Which highest microwave band (and supportive technology) might allow one to more readily generate a Spread spectrum signal? Is it TECHNICALLY possible to do that? How well can a signal be 'hidden' with such an approach?

You can use two LM317's - one as a voltage regulator, the other as a current regulator. See Nat Semi's website (www.nsc.com). To get down to "0" volts you have to "bias" the reference voltage on the voltage regulating LM317- this can be done with a band gap reference diode (or, you could just use the fact that an LM337 is exactly complementary - but it's an expensive fix.)

But any overtone crystal will oscillate at it's fundamental unless you
are using a circuit that specifically gets it to oscillate on it's overtone.

Rarely do you see a TTL oscillator used as an overtone oscillator. The
solution is to give up on TTL, and use a discrete transistor in an
overtone circuit.

There is a solution, but I can't remember the details. Years ago,
International Crystal had a circuit for an overtone oscillator that
was simpler than what was seen elsewhere. It had two capacitors
in series from base to ground, with the junction of the capacitors
connecteed to the emitter. That was fairly standard, though all
the other overtone oscillators had an RF choke between the emitter and
ground. Thr trick seemed to be in the value of the capacitors. I
looked at that circuit, and realized it could be translated to a TLL
oscillator. I must have needed an overtone oscillator at the time,
and wanted tokeep things TTL. YOu linearize a pair of gates, put the
crystal from the input of the first to ground. Put two capacitors in
series to ground. The output of the first gate feeds the second,
and the output of the second feeds the junction of the two capacitors.

It worked. I'm sure I must have used 470 ohm resistors as feedback
around the gates, but I sure can't remember the capacitor values. I'm
sure I used whatever values were used in the International Crystal
circuit.

I'd thought of sending the circuit into one of the ham magazines, but
I never got around to it, thinking it wasn't original enough. Some
time later, there was an article in Ham Radio with the very same circuit,

and he also dervied it from the International Crystal schematic.
I can't remember the title of the article or when it appeared (must
have been late seventies), but I think it was by Carl C. Drumeller.

Try tuning the circuit. Parallel connect 680nH and 68pF from
pin 4 to ground, but put a .01mF in the leg with the inductor, so
pin 4 is not dc grounded. That's a 0.68 microhenry and a .01mF
in series, in parallel with a 68pF from pin 4 to ground. Also add
maybe 10pF from pin one to ground. Add a small resistor, say
62 ohms between [the crystal / 680nH /68pF] and pin 4. Have
10 Megohms across the crystal? Add that. I have extrapolated
the LC values from a 36MHZ clock I used to have to fix, and
have not built your circuit. You will never get your third
overtone without some frequency steering. And without some
(expensive) synthesis software you will have to play around.
The resonant freq formula is 0.159 / sqrt (L*C). Use that on
the parallel resonant circuit components. Remember, the
moon really IS made of green cheese.

get a COMET CA-285 mobile antenna. Length=1.32m Weight=300 g Pmax=300W
it's designed for 6m (0dB) and 2m (3.4 dB). Works fine.

244. Low Power Design Wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-09 00:00:00 UTC
From: Duncan Walters <tesla@cwcom.net>
Message-ID: <38790397.C644F4AF@cwcom.net>
Source record: 64343

I want to build a simple no-frills basic CW transmitter for any single
HF band
40 thru 10m.
I want the design to power up from a very low D.C. voltage source (less
than 3 volts)
using just standard parts.
Has anyone out there got any circuit designs that I could use to form
the basis of
such a design, or could perhaps suggest a source of reference to such
circuits or schematics?
Any help or assistance would be greatly appreciated.
Please reply soon.

Folks, this restructuring stuff has made for a thoroughly-enjoyable flame war, but let's keep it out of the homebrew NG, OK? This is one of the few NGs unpolluted by all the pro/anti-CW rhetoric.

The guy asked a reasonable question that indicated that he wasn't just memorizing the question pool, but wanted to understand the material. I don't see where he's going wrong myself, and I hold an honest-to-God flameproof 13-WPM Advanced ticket from 1982.

Followups set to .policy, flame away...

Hi, Duncan,

There was an article in QEX in 1997 on very low-voltage (< 3V) QRP rigs.
It might be a good reference to consult. I can't remember the exact
issue, but a tour of http://www.arrl.org should turn up the article.

Good luck!

R,

Al W6LX

Source record: 64253

To the other replies I've seen, I'll add:
... Why not just use a single gate instead of a cascade of two? That cuts the delay. I use a single-gate oscillator with 74AC parts and never seem to have trouble with it oscillating (but see next paragraph). Of course, it also doesn't take as much DC feedback to get it in its linear region! Circuit is high-value feedback R, small R from gate output to xtal and a cap to gnd. Other end of xtal to gate input and another cap to gnd. Caps provide xtal load capacitance.
... Although I'd agree that an LC tank to insure oscillation on a specific overtone is very desirable, I can assure folk that it's not always necessary! I had to damp out the overtone oscillation in a 74AC fundamental mode oscillator. At least going that direction is easy and doesn't take a tuned tank.

Cheers,
Tom

251. Why put at 3.3M resistor betwen transformer pri and sec?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-10 00:00:00 UTC
From: wsanders at netcom dot com <exsvg@my-deja.com>
Message-ID: <85dm6r$s3m$1@nnrp1.deja.com>
Source record: 64254

I was RFI-proofing this Sony 6V power supply and noticed a 3.3M resistor placed between one leg of the transformer primary and the negtive DC lead. The PS is plain old unregulated DC supply with a bridge rect and a big electrolytic.

I use a Sony 7600G radio with the supply and the radio is unstable when the (unpolarized!) plug puts the resistor on the hot side of the AC. Removing the resistor had no effect on RFI but it did get rid of the 7600G's sensitivity to the orientation of the plug.

I can think of no reason for this to be there, except possibly to bleed off static charge from the device it's plugged into. Any ideas why they would have put this in? I've never seen such a thing in an schematic.

Since there aren't any locals (or you wouldn't be asking
here), you will probably want to build two stations to
make sure you have somebody to talk to. This also helps
when testing things.

While it seems to be grossly unfashionable these days, the
easiest and cheapest microwave mode is 10 GHz WBFM. I built
two stations for less than $CDN100. A nice wide band (500 MHz
wide) that's easy to use - who could ask for more?

265. Single-Crystal QRP Transceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-11 00:00:00 UTC
From: lagniappe <lagniappe@my-deja.com>
Message-ID: <85ft27$f4p$1@nnrp1.deja.com>
Source record: 64268
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

Looking for a kit, or fairly detailed plans, for a QRP
CW transceiver that uses the same crystal for both transmit
and receive. The scheme could be some sort of built-in
"pulling" capacitance to shift freq by a KHz or so on
synchronous receive, or some other design. Looking for
a very simple, small, low-power circuit.

thanks,

Martin

Have original AEA isoloop parts. Big black body cracked after too much UV and too many birds!

The band and variable cap with the stepper motor drive and controller box with power pack are available. All in good working condition. Even have 100 ft of controller cable!

Make offer, including shipping.

Obviously, CQ publications must be having problems, since they've also
eliminated their VHF magazine intended for communicators. Or perhaps
the death of the publisher last year is creating change, just as when
Jim Fisk died, and Ham Radio magazine changed.

I've seen QEX, and what's in it is okay, but it is rather small for
the money. There was a time when that sort of thing would fit right
into QST, without additional cost. I haven't seen QEX in years, because
the place selling it locally closed. I just can't justify the outlay
for QEX, not only is there the subscription price, but if you aren't
an ARRL member, then there's an extra fee, and if you don't live in
the US, there's an extra fee, and then of course there's the exchange
rate that brings it higher.

I wonder if this means QEX will change to be more like CommQuart, or
if the latter just really fades away?

I guess this explains the comment about a month ago about the ARRL
putting Ham Radio magazine on CDROM. At the time, it seemed like
a case of expertise and distribution; now it sure looks like the
rights to ham Radio were part of the package.

QEX has really improved over the last few years; it is bi-monthly now
with increased content. One could argue that QEX is already looking
more like CommQuart.

Yikes, if the entire library of Ham Radio ends up on CDROM, I'm going
to have get another cabinet to hold the CDs :-).

Hello--
From a free-lance writer's viewpoint, the CQ family of magazines has always paid its

writers very slowly-- sometimes, it took a year or more for them to send a payment check.

I'll greatly miss Communications Quarterly, though-- editor Terry Littlefield did an

excellent job, as did Peter Bertoni and the other technical advisors and contributors.

Sheesh.... at this rate, we're gonna wind up with only one hobbyist-related construction magazine, catering to audio/radio/robotics/model aircraft/amateur telephony
and tesla coils-- all at a level supported by whatever components you can still purchase
off-the-rack at Radio Shack.

Dark days are indeed upon us....

Hello--
IIRC, once upon a time Fair Radio offered a military-surplus cross-point meter originally
used in an aircraft glide-slope indicator. I don't know whether it's still available or what
the meter offered in the way of sensitivity, but perhaps someone else can help.

--> You may have to buy a stand-alone cross-needle SWR meter and take out
the "guts." This would have the obvious advantage of already having
properly calibrated markings for the power scales and the SWR nomograph.

Michael Covington, a Ham, who takes care of the Q&A column in "Electronics
Now" and may have some greater role in the magazine, started a long thread
a couple of months back in one of the sci.electronics.* newsgroup about
the impending merger of the two magazines. Actually, the merger was
incidental, but he was interested in hearing about what people thought
about the future of electronic hobby magazines.

Is 73 still around? It kept getting smaller, and less interesting,
and then it wzs sporadic here in Montreal. Then sometime last year, it
stopped showing up at the newsstands here. It appeared to be a cutback
in distribution, but it didn't seem all that healthy the last time
I saw it, so I don't think it's got much time left. Though Wayne
was on Art Bell last week, and seemed the same as always.

Greetings

I have a chance to buy a couple of each. Problem is I can't determine what they are. I can't find pinouts, datasheets, or anything on them. Are they simply non-ceramic versions of the 4CXxxx variety (like the 4X150 is to the 4CX250... etc) or are they something different altogether?

Many thanks!

282. Source for small value disc ceramic caps?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-11 00:00:00 UTC
From: John Burch <occupant@dtgnet.com>
Message-ID: <_3Ue4.732$0n1.2234@newsfeed.slurp.net>
Source record: 64285

I got "volunteered" for a (hobby) project that is
going to require small quantities (2-10) of small
value (5 pf to 25 pf) disc caps.

A short visit to www [capacitor] lead me to a few
sites where box car loads of capacitors are
available, but my needs are much more modest
than what the bulk suppliers are set up to handle.

Can someone recommend a small quantity cap
supplier?

Thanks for your time
John B
occupant@dtgnet.com

Please accept this as the courtesy note it is meant to be.

Most users of these newsgroups have agreed on the following
standards when posting sale or auction listings:

Please preface any auction posting with "FA:"
i.e. "FA: National HRO Coil."

Please preface any direct sale posting with "FS:"
i.e. "FS: Drake TR-4."

This allows those users who do not wish to see auction
postings to set their filters and thus, not see them.

Thank you very much for your help with this.

284. Re: Why put at 3.3M resistor betwen transformer pri and sec?

Newsgroup: rec.radio.amateur.homebrew

That resistor is in there for safety reasons. There should be a capacitor from the other side of the power line, also to ground. This was, I believe, mandated by some government organization to do with shock and fire hazard on power line operated equipment. It's been around for many years, and I think nearly every piece of consumer line operated gear has it.

Basically it prevents the chassis or user touchable metal parts from building up a high potential that could cause shock.

The last time I bought a small-cap assortment from Radio Shack, ALL the
packages were 60% values under 100 pF. Try that.

4cx1000 and 1500 are exceptional tubes. The 4cx1500b has outstanding 3rd order imd figures better than -40 db. The 4cx1500a has higher output power and higher plate volts requirements. The 4cx1000 is about the same as the 1500a and can be interchanged. I would select the 4cx1500 series of tubes for the higher plate disipation.

Dear Sir:
The tip off to that resistor being intended as some kind of a bleeder is it's extremely high value. The current through that resistor would be so low that an active circuit would almost not see it. However, I can't see why in the world, high value or not, someone would engineer a resistor going straight to the AC line. Since this is not my forte, why not ask the people who are the experts in this? Contact Underwriter's Laboratories (UL) in Northfield, Illinois. I'm sure that power pack is UL accepted and someone there could probably tell you exactly what the rational is in putting that resistor there or (stanger things have happend) if it's a mistake. I believe they have a Web site at: www.ul.com also. When you find out the answer, post it for all of us, so we can know the solution too. Yours, George, WA1PIX

From: mike pitoniak <michael_pitoniak@3com.com>
Message-ID: <38a139f2.31e1f6e7@usw-ex0107-042.remarq.com>
Source record: 64204

Hi Folks,

I am trying to construct a electret boom or lapel mike for my aviation ICOM radio. I have the schematic of the speaker mike they offer, and essentially have to reproduce the microphone preamp circuit shown. I am a little fuzzy on my circuit design, could someone give me a hand in reproducing the microphone amplification circuit with radioshack components?

I have a copy of the schematic, so if you can help please just send me mail and i will forward it. The tricky part of the circuit is the way the amplified signal rides on top of the supply vlotage for the circuit (derived from the radio plug). It is possible i could get away with a simple op amp circuit, but no one can figure out the gain i need.

many thanks,

mike

299. Plate Modulation -- Plate Current change ??

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-12 00:00:00 UTC
From: JGinNY <jgovost1@twcny.rr.com>
Message-ID: <387C8CF6.877EBB60@twcny.rr.com>
Source record: 64205
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.basics

When plate-modulating an RF amplifier (according to the ARRL Handbook) there should be no noticeable change in the plate current of the AMP when modulation is applied. This being due to the effects of cancellation from the next half-cycle of the modulated wave. Or something like that.

Somewhat confused here: Granted, a milliammeter cannot follow the rapid changes in the af (modulation), but then how/why can you "see" the plate current of a *modulator* tube kick up on voice peaks? The current variation is clearly visible there.

What is the difference between these two situations?

Many thanks for any help...
[Pls reply to newsgroup, or if directly, to <jwgbee@hotmail.com> (not the address above) thanks]

I.e.,:
Presuming that the modulator is supplying an increase in power (and
therefore current) to the plate of the final amp, why wouldn't it show up
as an increase ("kick") on the final's plate milliameter, as it does on the
modulator's plate milliameter?

thanks again for any comments/info

Mark,

I looked at the SP-1B as you noted, but it appears to me that
this radio is not a single-crystal rig. The illustration shows
two crystals on the radio. The "spider junior" appears to be
a single crystal, but if you read the ad copy you see that it
only uses the crystal for transmit - receive is not crystal-
controlled. As I noted, I'm looking for a scheme that uses some
sort of offset or pulling to get the double-duty.

Well, obviously you must be right within the US or Canada.

But, from Europe we are happy to have a separate issue for QEX (even though it might be thought as expensive), because mainly what is in QST does not really concern us. I find worthy to invest some bucks (euros over here) in QEX, I would change my mind if it were to become part of QST.

> the place selling it locally closed. I just can't justify the outlay

True, and I had planned to object to this particular point. I don't want to become an ARRL member, for what use ? I am in Region 1, secretary of a French-wide amateur radio association, so I am already pretty involved in all that regards European and French aspects of ham radio. It seems unfair to be charged for something I wouldn't benefit of in any case.

If plate current varies much, say more than 15% during the modulation
cycle, then the amlifier is being overmodulated (greater than 100%)
and distortion will be evident when the carrier is demodulated.
Listen to it.

Turn down the mike gain control until there is no variation in plate
current. Very likely the modulated amplifier is at present being
driven into behaving as a speech clipper !

If that cannot be done then the amplifier/modulator has been
incorrectly designed or has developed a fault. Check all DC plate,
screen grid volts and control grid bias volts.

Yes, the modulator does supply more plate current. But it also reduces it on the other half of the cycle, so the average current remains the same if all is linear.

The idiot would be pretty old by now. Contests started in the early
days. Of course, back then I don't think it was contesting for the
sake of contesting, but contesting to prove your equipment.

I don't know what the earliest contest was, but the one that comes to mind
was the Transatlantic Test back in December of 1921. It set out to
prove that those unwanted higher frequencies could bridge the Atlantic,
and surely required people to put some effort into getting theie
equipment in top-notch shape.

It's in more recent decades that contesting has become an edn product,
and one that often seems to require more stamina than technical skill.

Since hardcore techies are a minority in ham radio,
does it not stand to reason that there aren't many
hardcore techie magazines anymore?

I haven't seen 73 in a long time locally (Toronto),
and the last issues I saw were pretty anemic. I
subscribe to VHF Communications, and when its future
was in doubt was planning to flip a coin over Dubus
or UKW-Berichte (the German parent of VHF Comm-
unications). But that's sorted and I look forward
to seeing issue 1/2000 from the new publishers.

One of my faves was Electronics World (which started
life way back when as Wireless World) but either it
ceased publication at the end of last year or the Canadian
distribution deal ended. Sigh.

Magazines like RF Design are a gas if you can get them
for free. They're pricey if you have to pay for them...

What you describe sounds like what's already built into pretty much
every electret mic capsule. Are you sure you need more than that? It
seems unusual to add more amplifier stages external to the radio. But
if you'd like to send along a .gif (NOT a .jpg) of the schematic to me
at k7itm@aol.com, I'll have a look at it for you tonight.

Cheers,
Tom

You're right that with linear modulation with zero DC content, the current from the plate supply of the plate modulated stage will not change. You're also right that the RF power increases during modulation. With 100% sinewave modulation, you'll have 150% of the unmodulated RF power output. So what's going on here?

To begin with, the additional power is being supplied by the modulator, not the DC plate supply. So, from that standpoint alone, you expect the DC plate supply to keep supplying the same power. Since it (the plate supply) is constant voltage, you expect constant current.

IF your modulator output stage were class A (ouch!), then you wouldn't see a change in modulator plate current either, from no signal to full modulation. But of course, they usually are class B or AB, and at full output the plate current is greater than at idle, just as in a linear class AB or B RF amplifier.

So, what the heck is going on in the RF plate circuit/modulator? How can you analyze this and understand how the average DC current can remain the same but the power increases? OK...in an amplifier that modulates linearly, the RF output voltage (RMS, or peak voltage per RF cycle) will be linear with instantaneous plate supply voltage...that is, as the modulator output swings the plate supply voltage up and down, the RF voltage will track that proportionally. So will the instantaneous current supplied to the plate. Now, to make things simple, let's think about a 1000V DC plate supply running 500mA...500W. Let's say the amp is 75% efficient, so the output power is 375 watts, no modulation. Now...apply a square wave modulation, at 100%, so the plate voltage spends some time at 0 V and some time at 2000V, with quick transitions between those levels. At 0V, the current is also 0. But at 2000V, the current is 1000mA, for 2000W. The _average_ current is still 500mA (since the duty cycle is 50% in the square wave). But the _average_ power is 1000W, twice the unmodulated level. Since average current is 500mA and the plate supply is constant at 1000V, it's supplying 500W, just as before. Is the modulator supplying the other 500W? Well, it MUST be. Can we see that? When the plate voltage is zero, the modulator is outputting -1000V, and must be subtracting 500mA from the average, so that's 500W during that half of the cycle. On the other half of the cycle, it's outputting +1000V at +500mA, so that's also 500W. The modulator average power output is 500W... it doesn't go back into the RF plate supply; it goes into the amplifier plate circuit and gets converted to increased RF power.

If you replace the square wave with a sine wave, you can do the same averaging by doing an integral over a cycle, and you'll see the same things happening, but at a lower power. Now the peak of the modulating sinewave is +1000V at +500mA, but the RMS values are 707V and 354mA, for 250 watts of power. And "real" modulating signals generally are less than that in RMS, even though the peaks are still nearly the same in a properly adjusted transmitter.

Hope that helps!

Cheers,
Tom

324. Wireless FM Tx module for 1200 Baud.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-12 00:00:00 UTC
From: Moses Clark <itek@sybercom.net>
Message-ID: <JJ6f4.9360$T2.8608646@firenze.visi.net>
Source record: 64230

Greetings,

(Do I really need a radio modem ??)

First of all I have to say I don't know much about RF but, learning...

I am trying to put a little telemetry applications together.

The data is generated at 1200 baud in a TTL level.

I am wondering if I can put this data through the microphone lead on one of those miniature FM transmitter you can find in many different kit shops.

I am going to receive the data using matching speaker jack of the receiver and connect to a PC serial port.

The distance I am trying to work with is one(1) to Five(5) feet and again the speed is 1200 Baud TTL serial signal.

Thank you very much for your help.

Brian

Martin

The SP-1B has two crystal sockets, but this is to provide you with two transmit frequencies (on the same band). You don't have to install both crystals. There is a DPDT switch to select one or the other. The receive tuning is actually RIT and is achieved by a pot connected (through some other components) to the crystal, so I suspect that it is some sort of 'pulling'.

Subject: OEM "T" power connectors and Anderson Powerpoles

I have started a new web site to sell the hard to find and "elusive"
Anderson Powerpole connectors that have become (or are becoming) the most
popular power connector for interchangeability in the emergency community
along with Yaesu, Kenwood and Icom mobile OEM "T" power connectors.

www.powerwerx.com was started with hearing the concerns of hams across
the country in newsgroups of "where to purchase these connectors" and other
"hard to find" products at reasonable prices.

PowerWerx.com encourages groups to pool their purchases to obtain a very low
price on power connectors.

I apologize for the commercial promotion, but I feel that an on-line secure
source for these products has not been available for quite some time.

We accept MasterCard/Visa.

The philosophy of "one ham helping another" is now extended from my web site
to you.

But the reason the meter *does* kick is that the voice modulating signal
isn't either a 50% duty cycle square wave or a symmetric sinewave.
Part of this is due to the nature of the vocal waveform itself. It is complex,
often asymmetric, and most definitely not a pure sinewave. Another part
of this may be due to distortion products introduced in the speech
amplifiers, or in the modulation process itself, ie you could be flattopping.

It isn't unusual to see *some* variation in the plate current under modulation
simply due to the characteristics of the vocal waveform. But if you're seeing
a lot, you've probably got problems. An exception to this would be a transmitter
using controlled carrier modulation. In that case, you do see plate current
variations with modulation *by design* (carrier amplitude is varied so that
it is just sufficient to prevent overmodulation at any modulating level). This
is perfectly normal behavior for this type of transmitter. A few amateur
rigs do AM this way.

You can do direct FSK, which is what you're describing. But there are
a few caveats. You should have a direct DC coupled connection to the
FM modulator, and it needs to be true FM. If the transmitter is actually
phase modulated (and many are), you'll have problems unless you use
a data scrambler to keep the average DC level near zero.

But the simple wireless mics usually are direct FM, so all you have to do
is go directly in and attach your signal to the modulator varactor. You'll
need a resistive divider to knock the TTL down to the level required to give
you the desired FSK shift of the transmitter. (Plus and minus 75 kHz for a
simple FM wireless mic used with a FM broadcast receiver.)

You will also need a slicer circuit at the receiver to recover the signal
voltage swings coming out of the receiver discriminator. This also means
you need a direct DC connection to the discriminator. You can't just take
the signal from the speaker or headphone jack. (Actually this circuit isn't
really a slicer in this case since you want to directly feed a PC RS232 port.
What it has to do is amplify the voltage swings out of the discriminator to
at least +/- 3 volts and invert polarity to conform to RS232 specifications,
ie a 1 is a negative 3 to 12 volts, a 0 is a positive 3 to 12 volts in the RS232
spec.)

It will be useful if the receiver has a squelch circuit you can modify to
provide DCD to the PC. Otherwise it will be trying to read interstation
noise when the transmitter is off. This random data could cause overruns
of the PC serial port UART.

While the surgery to the radios is usually relatively minor (though it can get nasty with some radios), and the slicer is easily made with a single opamp, you can avoid having to modify the radios if you use modems.

The modems (Bell 202) will generate and decode two different audio tones representing 1 and 0 respectively. So you can simply feed this audio signal into the transmitter microphone jack and out the receiver headphone jack to the receiving modem with no modifications to the radios.

Bell 202 modems are available as a single chip with TTL inputs and outputs, but you will need a TTL to RS232 conversion at the receiving end to drive the PC serial port. That is also available as a single chip. So at the transmitter you need one chip, at the receiver you need two. Plans to build Bell 202 modems have appeared in the ARRL Handbook and other places.

Either method will work. Using the modems avoids having to modify the radios. Doing direct FSK is conceptually simpler, but there are some practical problems which usually mean you'll have to fiddle with it a fair bit to actually get it to work right. The modem solution is nearly plug and play.

Hi, Gary,

For the curious who want to see what you're talking about here, check out the article entitled, "Lop-Sided Speech and Modulation," by George Grammer, W1DF, QST for February, 1940. It deals with just this scenario and points out the distortion that can occur in an AM transmitter if attention is not paid to voice wave polarity.

R,

Al W6LX

It is two meters together. (duh) If you're on a homebrew kick, just get two surplus meters that are the same and fabricate your own scale. Better yet, make it an active meter and design a circuit to calculate the VSWR and display this on one meter.

MC.

Source record: 64293

Hi,

I'm looking for the pin description of the ALPS sat-tuner module BSJE3-1D1A.
I hope this is the correct part number. The second number on the module is
3N1521A.

BTW: What's the IF frequency of such tuners?

Peter

Hi Brad--

The worst part was the way you were made to feel like a worm for even bringing it up. Or lied to about when the payment would actually arrive.

I was VERY naive about this and trusted them.

I had to wait up to 18 months for payment. That was it: I withdrew all my MS's.

Peter Taylor dropped his column for the same reasons.

Treating your writers poorly is a formula for disaster, obviously not a lesson learned properly.

Comm Quart had its problems and had its moments, but its path to 'defunct' could have easily been avoided by using the writers to generate more subscribers. Instead it relied--heavily--on the --opinions-- of just a few people, and now those people aren't part of QEX/Comm.Quart.

I don't think we should confuse inappropriate judgement with 'dark days upon us'. We, the buyers of ham magazines, determined this outcome ourselves. The people have spoken--through their wallets and pocketbooks.

No one is a victim of circumstances here--economic times are booming and people can afford a Comm. Quart. at the newsstand. The question has instead become--why? As in why bother?

I bet QEX now grows substantially as fresh efforts are being made to revive it, and a great new editor takes charge.

Best of luck to ARRL in the enterprise!

If you are referring to Popular Communications, I gave up on that magazine years ago. It just doesn't have any -bite- to it. It seems to be aimed at joe-newbie SWL more than anything else. Nuts & Volts is a good one, but I haven't seen it around in a couple of years. If they are still going they should invest some money in marketing.

Reduced prices and improved, much easier to read format.
http://www3.sympatico.ca/aquariusr/sale1.htm

A friend has set up a web site for me to sell off a 28 year accumulation
of electronic components including:
a Coaxial Power switch,
RF power and other transistors, RF I.C.'s,
1N3712 Tunnel diodes,
1N5711 Schottky diodes,
Ceramic 455kHz and 10.7MHz filters,
Minicircuits mixers,
variable capacitors, both panel mount shaft type and trimmer
variable inductors and coil forms,
High voltage vacuum relays, rectifiers, resistors and capacitors,
Other capacitors including, Photoflash, polypropylenes, and tantulums,
Switches, such as foot switches and industrial limit (micro) switches,
Ferrites beads and cores,
Transformers and inductors,
and lots, lots more.

Every tube AM broadcast transmitter I ever worked had plate current
kick under modulation. In theory you would not have this for linear
& symetrical audio. However voice &/or music is not symetrical and
inthe case of broadcast the audio processing is purposley
non-symetrical. Broadcaster try to reach +125 % -100% modulation
peaks on a mono AM station. 5% less for stereo operation...

So is you turn down the mic gain on your 3880 Khz station until that
pair of 3-500Zs you are running in the final, don't have any *Kick*
you will not be hitting any where near 100% on peaks.

the 4X1000 and 4X1500 most probably are a glass seal version of the
CX tubes. Neither of them is listed in current Eimac/Varian literature.
However, I own some 3X2500's. They are glass seal tubes and also are
no longer listed. So, should you buy them? Well, glass seal tubes tend
to 'gas' a little quicker than ceramic. What is their age and service
record? Will they glow like a mercury lamp when you fire them up?

Most of the 'PR' tubes are radically differant from their 'rf'
brothers. Compare the ratings and looks of a 4-250 to a 4PR250.
Monsterously differant. However, strangely enough, the 4-400 and
4PR400 are almost identical in construction. The filament ratings
are identical, but i suspect the 4PR400 has a much higher 'peak'
emission capability. You have picked the one tube that is very
similar, and may be a good swap. I have not however tried it.

O.K., there were several answers all similar stating very little
change in 'plate' current. I observe this to be true. In practice
if I see 1 amp at 0% a.m. modulation, I usually see 1.1 amp or
slightly less at 100% modulation. But, would you like to see the
effects of modulation on your output power? Look at the 'antenna
current', or 'common point' current meter. Or, here is something
else, suppose you only have a 'cathode current' meter, and not
a 'plate current' meter. The cathode current behaves similar to
the common point current meter, and does deflect upward, I seem
to recall about 15% or so on music.

The best tech magazine was "Ham radio"(vale). What a pity this one went under, it was crammed full of different articles. I think this is where QEX is a let down, it has so little and is poor value for money. Why cant they put those same articles in QST? They seem to be elitist in their thinking. Besides most of the article of technicle substance would not make QEX or QST, since it seems that the editors seemed to be controlled in the favour of the advertisers. Anything critical of good design and anything that points to the crap sold by the manufacturers seems to get killed. The ARRLS favourite company seemed very prominent in the recent license changes. Did any ARRL members get a courtesy letter asking them?

I have a complete S-100 desktop box.
It has a Z80 processor at 6MHZ and
64K of ram and dual 8 inch floppies.

It worked the last time I plugged it in.
That was about 15 years ago.
I can't remember the brand.
It was not one of the early famous brand names.

Anyone interested?

Got a 110V-to-600v transformer in a small 60's vintage transceiver; may be blown. There was a short in the pwr supply at one point, big sparks and lots of smoke!

Black deposit on cloth covered leads, just where they exit the metal tfmr housing.
Still appears to yield proper voltage on secondary, and rig receives fine, but loud raspy hum in audio on transmit.
(btw, All new replacement filter caps in pwr supply circuit.)

Is it likely the transformer is damaged, and could it be in part causing the 60 cycle crud?

tnx.
J.

I would not condem the transformer just yet. When the 'main'
portion of the power supply smoked, you may have fixed the 'obvious'
but look farther. Did it also wipe out a bias supply? What about
caps in the screen supply. Maybe one of them opened during the surge.
How about any resistors in the center tap to ground. Just to many
possibilities to mention after a power supply melt down. Perhaps
on side of the bridge is open. That would give clean power for receive,
but under high current demands of transmit, you would have more ripple.

Yes, I was going to make a comment that the "cheap foreign crap" should not be confused with the "very high quality foreign parts" that I more commonly deal with. Don't look too closely: the Motorola parts may well have been made in Taiwan or some other country. The Burr-Brown OPA2134s in my hand were made in Taiwan. Same with the Texas Instruments TLC555s. I recall having to wait a week for samples of the National LM6172 (IIRC) because they had to be shipped from overseas. I wonder if the AKM5352s I have here were made in Japan, Korea, Taiwan, or maybe even the US. It's a global economy, and those unwilling to acknowledge it are the poorer for it, IMO. (I still sometimes use a frequency counter I built from PolyPaks floor sweepings in the early 70's, so even cheap foreign/domestic crap sometimes manages to be OK! ;-)

Cheers,
Tom

Hello--

Poly-Pak sold rejects, end-of-production lots, contract-termination components and other
surplus-- sometimes, one could find real bargains in a package, but all too often the
purchaser received the rejects. Poly-Pak's slogan was, "We bot (sic) thousands... no time
to test!". Poly-Pak may have had no time to test, but the manufacturer did....

My favorite item: optoisolators P-P advertised as , "sensor or emitter may be good-- o
both" <giggle>.

Poly-Pak was located in Wakefield, MA, not far from Transitron Co.-- which supplied many
of P-P's "bargain" components. Transitron did not enjoy a good reputation as a
semiconductor supplier, IIRC.

But even the best vendors screw up-- a company I once worked for as a components engineer
used Motorola's 68000 processors, which were in short supply in the early 1980s. One day,
we received a shipment, and my inspector called me. "I think you'd better have a look at these..."

Devices in the shipment either carried no stamped part numbers, or were clearly stamped
"REJECT" in big letters. Motorola had shipped us the jeject bin's contents in order to make
the delivery commitment. So, even Zeus nods-- cut him a little slack<g>.

73,
Brad AA1IP

I've always found that macromodels for other than op amps are fairly rare. When I need something like that, I can generally make some reasonable engineering simplifications and put together my own model that works well for the particular application I'm working on. If you don't find a model, you might consider that.

Cheers,
Tom

Hi folks,

I have a brand new Hammond modulation transformer model 2310
that I need connection info for please.
I have contacted Hammond and they say they don't have a file on it.
It's too old. If you have an old catalog from the 40's- 60's and have
a moment to look up what the 12 terminals are, I would be very grateful.
Z ratio, power, pri/sec Z etc.

Thanks,

Paul

a very common quarterwave line circuit using a Unitrode UM9401 with bias during transmit will work (two smaller diodes in anti-paralell on RX side,2* BA282 or similar will work), it does not hurt to feed the current through the diodes on TX port ant RX port, but if you wish to use higher power, say 5kW, you may still use the Unitrode diode, see SM5BSZ's site. You may search for SM5BSZ or G3SEK, it is a path from G3SEK's site

it is principally possible to use a quarterwave line circuit on 2m for 70cm, the coax cable length are not at all critical, but must be n'th odd order quarterwaves on 70cm, not too close to even order.

Have seen some very accurate calculations for 2m lines (switches up to few hundred watts), they are probably described by somebody who haven't tried more than the one described, and have probably not measured any losses. I have made and used almost a douzen two metre switches and a few for 70cm packet radio.

Cheers, Leland. Nice to see a really helpful post to a ham in need!

After a number of false starts, I followed out your equations and got the
right answer, too.

In parallel, the bigger the resistance, the higher the Q,
in series, the higher the resistance the lower the Q

So all is as expected!

Source record: 64175
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.basics

I'll stand by my original statement, with one clarification. "Will not change" should be taken to mean that the average value stays constant. Any transformer-coupled modulation-even assymetrical voice waveforms-will have zero DC content, and a change in the average (DC) current from the RF amplifier plate supply must be because of nonlinearities (or time variations) in the modulated amplifier, perhaps because of overmodulation. You'll see the plate current meter move--flicker--if the modulation frequencies are low enough compared with the meter movement's ability to track change, and you'll see it move if the amp isn't perfectly linear under modulation.

*** But in any event, the key point of my first posting in the thread is that the RF power output will change drastically more than is indicated by the (average-reading) RF amplifier plate current meter. My square-wave modulation example doubled the RF output power; there certainly is not anything like a doubling of the plate current in any amplifier even remotely close to linear under those conditions. For 100% sinewave modulation, similarly, you might see a few percent change in the plate current because of nonlinearities, but not the 50% change that would be implied by the 50% increase in RF power output. ***

Clearly there are all sorts of nonlinearities that can come into play: an RF stage that's incapable of +100% modulation, trying to drive to more than 100% in the negative direction, and "controlled-carrier" systems that change the operating conditions of the RF stage to increase carrier power during modulation. But again, the point is that with a linear system, you see increased RF output power with no increase in RF plate supply DC current, and the additional power comes from the modulation audio signal itself.

Cheers,
Tom

Communications Quarterly is the successor to Ham Radio. How well it's filled those shoes is a matter of opinion, but most I've heard seem favorable.

QST has the unhappy and impossible job of satisfying the extremely diverse interests represented by the ARRL membership. It might seem to readers of newsgroups like this one that everyone is interested in technical matters. In fact, though, only a tiny fraction of amateurs are really interested in technical material of the level found in QEX or Communications Quarterly. So putting this material into QST in place of content which is of interest to a much larger fraction of the readers would be a foolish thing for the ARRL to do, much as you and I might like it.

All prices plus shipping from 07657.

1.) Pair of Bogen MO-100 monoblocks. These are the early version that uses 6550's, rather than 8417's. With mounting rack. 100 watts/channel tube power amps. Sound great--recently rebuilt (3 months ago) with modern electrolytics and Svetlana 6550C tubes. $350 for the pair.

2.) Good, used, tested Amperex ECC88/6DJ8 "Bugle Boy". Pulls from test equipment. $10 each

3.) RCA 810 triode. JAN type CRC-810. Pull from unused equipment. $40 --With Johnson socket and Triad F-33U filament tranny $55

4.) Penta Labs PL-254W Triode. Pull from unused equipment. $25

5.) 2 pcs 4E27A/5-125B pentodes. 1 Eimac, 1 Sylvania. Both are NOS, but Eimac box is missing. $30 each or $50 for the pair.

6.) Westinghouse 5CX1500A pentode. Pull from working equipment. Tube tests good. $75

7.) RCA radiotron UV-201A Used, tests good. Brass base early triode. With bakelite "breadboard" socket. $30

8.)Modified Techron 8521 power amp in roll-around 19" EIA rack. Can deliver
over 5kW into a 2 ohm load. Frequency response DC-50kHz. +/-140V output.

Unit was a pull from an MRI scanner, and has been modified to operate from single phase 208-240 VAC power. All modifications professionally done. (Original xfmr, filters, rectifier removed, and replaced with fully rated single phase equivalents) Possible uses:

Motor driver
ELF transmitter
Shake/vibration testing
Stadium/Concert hall PA system
General scientific research

Or use it as the biggest subwoofer amp on the block! Just the thing to wake the neighbors up! :)
Best offer over $700 takes it. Unit is located in Northern NJ, and will deliver within 50 mile radius, or you can pick it up. This thing is HEAVY, but will ship via truck if desired (at buyers expense for shipping and crating).

9.) HP 651A Audio Oscillator. 10Hz-10MHz sine wave. 19" Rack Mountable
Good condition. $60

10.) Boonton Radio (HP) 202H RF generator 54-216 MHz AM/FM Rack Mount
Good condition $50

11.) Tektronix R5103 oscilloscope. Mainframe is in good working
condition. Accepts all 5000 series plugins. Comes with 5A16 dual trace
amp and 5B10 timebase. Plugins need work. $25

Thanks for the Bandwidth...

Jim -

TO-92 (plastic) 2N2222 (mostly sold as PN2222) are dirt cheap.

TO-18 (metal lcan) 2N2222 are far more expensive than $.025 each.
Been a while since I've priced them, but as I recall, in high volume,
they run around $.18 each.

For a couple of years now, Radio Shack has sold a bubble pack of several dozen very small disc ceramic capacitors, with values ranging from 2 to 33 pF, for $1.98 or so. This is one of the greatest RF bargains of the century in my opinion, and definitely qualifies as one of those rare instances where Radio Shack Did Something Right(tm).

I make it a habit to buy every package of those capacitors in sock every time I'm in a Radio Shack store, just out of fear they'll come to their senses and quit selling them. :-)

It's very common to have the wafer fab in the US, but have the packaging
and testing overseas. And if slicing&diceing, bonding, molding and testing
adds more to the value than the cost of the original die, they have to
stick the other country as the country of origin.

we used to buy "cheap foreign crap" from Polypak some years ago,
believe it was made in America, later we got low-priced but high
quality European semiconductors

anyone have a good, relatively simple circuit for a quality bench
power supply with adjustable voltage and current...about 2-30V and up
to 2 or 3 amps??

I have the ARRL 1997 handbook circuit but it seems to me to be more
complicated than is really necessary. I'm thinking of something built
around the LM723....

If you're not big into protection circuitry and having real current
control with a pot is not an actual need, an LM350K will do the job.
So will an LM317 driving the base of a 2N3055. You can current-limit
with an emitter resistor as well as with a suitably small transformer.

I've had a very crude adjustable supply in use for some 15 years,
based on an LM317T. It gives me about an amp from 2 to 37 volts,
and appears to be indestructible. Someday I may have to change
the filter cap for something manufactured in this century...

Somebody posted on rec.radio.amateur.homebrew a few days ago about a
circuit using two LM317s, one controlling voltage and one controlling
current. He cited National as the source, so the circuit may be in
the National Linear databook or on National's web page.

Probably tar, put there when the transformer was made. I remember being put off by seeing that on just about every new transformer of reasonable capacity I saw during the 60's and 70's.

> Still appears to yield proper voltage on secondary, and rig receives
> fine, but loud raspy hum in audio on transmit.
> (btw, All new replacement filter caps in pwr supply circuit.)

1. "New" doesn't necessarily mean "good". Try parallelling each with a tubular (preferably powering down while attaching and detaching it, unless you like sparks).

2. If you wired the new caps in parallel with existing cans, parts of the cans may have high power factor rather than just being low in capacitance; this can cause problems too. If that's what you did, try getting each section of the can out of the circuit for a test period to see if that helps any.

> Is it likely the transformer is damaged, and could it be in part causing
> the 60 cycle crud?

I doubt it very much unless the thing stinks to high heaven or gets really, really hot in a short time. Those older transformers were built to stop speeding trucks and power entire cities. :-)

Ham Radio University - HRU2000
Babylon Town Hall Annex
Phelps Lane & Miller Ave
North Babylon, NY
Sunday January 23, 2000
9:00 AM - 2:00 PM

This is a special day of education for amateur radio. Many ham radio Clubs and organizations from the New York City-Long Island Section will have information booths. This is your opportunity to meet the local clubs and organizations and learn their activities, meetings and membership. There will be a free tune-up clinic, DXCC & WAS card checking, eye-ball qso room, a full VE session along fifteen technical forums with guest speakers from the NLI section.

Donation: $2.00. Spouses and children under 12 will be admitted free.

For more information via Internet: http://arrlhudson.org/nli/hru2000.htm

Contact: Phil Lewis N2MUN (631) 226-0698

FORUM SCHEDULE
10:00 - 10:45 AM
Session 1A -Amateur License Restructuring - George Tranos N2GA
1B -Packet- John Papson WB2CIK & Bob Anderson K2BJG

See the LM317 data sheet, in the "typical applications" section.
There's one labeled, "5A Constant Voltage/Constant Current Regulator."
The diagram shows output 1.2V--30V. Lots of other ideas in there, too.

Cheers,
Tom

Hi;

Repair shops / tube audio gurus / radio buffs take a look!

One lot of tube shields for the 9 pin miniature tubes (12ax7,
12au7...etc) these are the twist-lock spring-loaded type used in
radio and tube audio gear.

There are over 300 in the lot and the current bid is $15.50. I have
seen these go for over a buck a piece at hamfests and over $3.00 each
on the net.

Stock up now!

Don't miss out on this one!

O.K., there is almost no way to know the 'mix' or 'perm' or
anything else. But I have created baluns, rf chokes, and all
kinds of 'as needed' broadband rf transformers. I have been able
to easily get 14 turns of kynar coated 'wire wrap' A.W.G. #30
through the 'hexagonal hole' in these little devils. Just find
some junk 455khz i.f.cans (the old kind) and remove the tuning slug.
I have had nothing but success so far.

Steve Huss wrote in message ...
+AD4-I've got a couple boatanchors that I plan on keeping for a long time
(Drake
+AD4-and Hammarlund). Every once and awhile I see someone advertising for a
+AD4-replacement P.S. transformer. Is this the result of one going out in
normal
+AD4-use or is it due to big time failure of the filter/bypass caps? Can
+AD4-varnished wire wear thin after 50 plus years of service?

If you want to keep the old transformer running, keep it cool and keep it dry.

A rule of thumb in chemistry is that reaction rate doubles for every 10 degrees C rise in temperature. Experimental work in the 1930's demonstrated that transformer insulation and such double their degradation rate for every 8 C temperature rise. It is good practice to keep the transformer temperature below 60 C (140 F). This is approximately the highest temperature where you can touch and hold your fingers there.

This is why in old tube gear, I always use solid-state rectifiers. The reduction of typically 10 to 15 watts from the filament winding allows the transformer to run a little cooler helping to compensate for its age. Most old radio designers knew little about heat transfer and many old radios run absolutely far too hot. Note that when silicon diode are used rather than a tube, you may have to add a series resistor to keep the voltage at the old level. The heat dissipated by this resistor is exactly the same as that produced by the plate dissipation of the rectifier tube. But you often have some control over where this resistor is located giving you better heat transfer. A small fan will work wonders in keeping old gear cool.

Proper fusing generally takes care of capacitor failure as a transformer can usually take a very high overload for a very short period of time (until the fuse blows).

No one has mentioned variation on the final plate current due to poor B+
regulation. Many plate modulated transmitters use common B+ for the RF
final and modulators. Some older ham transmitters had as little as 4 uF
of filter capacity. The dynamic regulation of these supplies was quite
poor.

Sure this works but ... those old 455 IF cans are probably a lot more valuable now than a few ferrite cores. I'd trade brand new ferrite cores for old IF transformers most days of the week. The balun cores (two holes) are less than a half a buck.

This is a device for measuring forward or reflected power, also known as a directional coupler.

Ranges:

Forward - 200W & 2 Kw
Reflected - 200W & 2 Kw

Frequency: 2 Mhz to at least 30 Mhz

There are 3 parts: the power sensor, which is a metal block 6 cm x 6 cm x 4.5 cm, the meter (7.5 cm square) and the range switch. The power sensor has 2 N connectors, power in and antenna and 4 feed-through connections to the range switch.

The meter scale is non linear. Center scale low range is 80W, high range 500W.

This is the same assembly as used in the Collins KWM2 series of transceivers, and was removed from a piece of test equipment.

In excellent condition, completely wired, with wiring diagram, and ready to mount into your equipment or a small box.

Shipping weight approx 500 gm.

Best offer takes it.

John Mackesy VK3XAO

PS - it's NOT a dummy load!

I must agree with you on that issue of not destroying older
valuable parts stock. In thinking back, most of my slugs (and
I have a large tray of them) came from early to mid seventies
tv receivers that were tube type. I yanked the slugs from the
i.f. strips before i junked the chassis. This would also explain
why the slugs work so well for me, as almost all of my experimenting
is limited to 14-30mhz, and the slugs would have been designed
for 40-45mhz operation. Just wanted to clear up a messy post.

Excuse this Third World slave's "limited comprehension" - I would like
to buy a made-in-USA dynamic RAM, but it seems they are all made in
Japan or Korea. And I mean the chip itself, including the R&D, not just
the packaging. When they got over 64 kbits the USA got left behind and
stopped making them.

Well, did you check the spelling on your own "devises" above? If we
assume you have a perfect grammar and spelling, according to my
"Webster's Unabridged", you meant either:
1) a gift of real property by will; or
2) a will, or clause in a will, granting such a gift.

Hello,

I'd like to use David Clark H10-20 (or the H10-60) headsets with
ham transceiver. They have electret microphone that needs a DC bias
voltage applied.

Anyone have a schematic of audio circuit of aviation transmitter? Or
some thoughts on what circuitry I might kludge together to build
an interface?

Many thanks,

Alan, W3DVX

Suggest one way of checking the txfr would be to disconnect ALL
connections, use multimeter to identify windings (if they're not shown)
and then Megger between the windings (UK speak for checking insulation
resistance - my hand cranked Megger Insulation Tester shows no signs of
giving up the ghost so why should I join the 20th century ?). If
everything looks OK connect txfr to mains (still off load) & monitor
primary current, should be virtually 0 unless some of the turns have
gone s/c. If you've got shorted turns then, as well as drawing current
off load, the txfr will start to get warm and (might) make buzzing
sound, although this can be due to loose core laminations. Additional
fuzing in the primary might well be a prudent measure in case of a
really good 4th July type of s/c. If it was me I'd be looking for an
insulation resistance of a lot better than 0.5M; if the txfr is potted,
wax impregnated and/or sealed then there is not much you can do to fix a
s/c turn but if you're lucky & can take the txfr apart then rewinding is
a simple (but tedious) option. I'm probably teaching my granny to suck
eggs and far better ways for testing txfrs must have been invented since
I last showed Marconi/Edison how to use a multimeter but you never know
...... hope the info is of some use.

And the editing. Everybody's writing benefits from some critical review,
which you get from an editor when you're writing for a good magazine.
However, it's totally lacking from most articles published on the web.

It's also lacking from a lot of the 'advertorial' articles in the free
professional magazines.

In the discussion groups, articles usually tend to be ad hoc and extemporaneous. In a published article the author has wrestled with his material at much greater length, perhaps months or even years. On the internet we all need to be tolerant of quick responses. One thing I like about discussion threads is that insight and knowledge improve, errors get fixed, as the threads proceed.

AMEN! Shout it, brother!!

Having edited my share of articles for a controlled-circulation trade mag, I can testify that
the incoming-manuscript slush pile contains several advertorials for each solid technical
manuscript. We generally don't get too alarmed by poor grammar and spelling-- that's what editors fix-- but puff pieces for someone's components or instruments raise a red
flag.

Body handling: Binary attachment payload not displayed: vcard.vcf

We now have a source for raw amorphous solar
panel material. This is raw stock rated
various voltages and various current levels.
Different sizes and configurations available.
No leads.

This product is ideal for the hobbyist who wants
to experiment with solar power or for the cheap
skate who can't stand buying retail. Just solder a
wire to the positive and negative ends and place
the panel in the Sun. DC power on tap.

That's because now only power-of-1000 prefixes are officially
encouraged, so you're supposed to say "10 m" rather than "decimeter".
In the same way, 100 mm is "in", while 10 cm is "out".

430. LOW PASS filters -who makes them and who has schematics?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-16 00:00:00 UTC
From: Curtis Scholl <cscholl@izzy.net>

Hi Group!

I think I may need a LOW PASS filter to keep my emissions from interfering with the TV next door.
Here is the situation from the evidence presented so far.

Last week I had a multiband (multi dipole) inverted antenna up about 16 feet. It started looking very ugly so I built a multiband (three different quarter wave) vertical. Last week I received no complaints. This week I am told that my antenna is radiating into her TV. She hears my call sign on the unit with a fancy cable box in the living room. She does not hear me on the non cabled TV in the back room. Yesterday she did not hear me either and the verticals did not have a "counterpoise".

This morning I ran some 10/15 foot wires from the central ground point of the antenna out to a distance of 10 feet give or take to make a "ground plane". Now she hears something in the cable box.

Is there enough evidence here to suggest that the cable for the TV set is underneath my counterpoise? Or is the power line being invaded by my signal? If it were the power lines being polluted, would not the older TV in the back room be affected?

Would a LOW PASS filter that would allow nothing above 30 MHz to pass be sufficient or would anyone suggest moving the ground wires around?

I'm doubtful that a low pass filter on your transmitter will do any good. This sounds like typical fundamental overload to me. If you were radiating harmonics, they would show up on specific frequencies, and would move as you tuned to different frequencies. That doesn't sound like what's happening. The fact that the over the air TV is unaffected reinforces this conclusion.

You're just coupling enough amateur frequency signal into her cable box to cause this symptom. What you need to figure out now is how it is getting in, and how to stop it. (Actually, it isn't legally your problem. It is the cable company and your neighbor's problem. But trying to be helpful in solving the problem is a good neighbor policy.)

The signal could be getting into the cable box either via common mode on the cable or via the power line. Since the problem didn't exist when you were running a horizontal antenna, but does now that you're running a vertical, you need to look around and see how the relationship between your antenna patterns and the cable and power lines have changed. It is likely that you now have a current loop paralleling one or the other now when you didn't before.

Unless you want to change your antenna system again, you can try ferrite filters on the power cord and cable at the offending cable box. (Providing the neighbor will let you do that.) There's no filter you can add to your transmitter which will help.

I sincerely doubt your problem is harmonic radiation- this being the ONLY problem that an LPF would solve. Sounds more like fundamental overload of the TV (HPF) or common mode (ferrite chokes).

A properly operating cable system would not pick up radiated signals.
However, I'd say your neighbor will need to install an AC power filter. She
may need to filter not just the cable box, but also devices hooked up to it.

I had a problem where the audio from my transmitter would come through the speakers on my television, hi-fi vcr, stereo with surround combination if I have the dolby surround "ON". The television receives it signal from a yagi on the roof. I use a R7 vertical not too far away. The interfering sound is not to loud and goes away when I turn the Dolby surround "OFF". My transmitter does interfere with the television picture a little mostly when I am on 20 meters phone and the television is on channel 4. I have tried Radio Shack and Vectronics HP filters on the TV and VCR and wrapping the speaker wires with ferrite but it does not seem to really help. The Vectronics has both a HP filter and ferrite core for common mode. It is not that bad of interference but I would like to get rid of it. Do you think wrapping the AC cord with a ferrite filter would help? I am only concerned about the sound interference. I guess I could try the old LC 100 uH choke and .001 uF shunt cap on the speaker side trick. I hate to go through all that work to see that it does not help one bit.

Since my shack is in the basement I use a cold water pipe for ground. I have a ground rod next to the R7's antenna mast. I strap the ground rod to the cold water pipe also. I also have a Alpha Delta Transi-Trap lightning protection device in-line with the HF cable. The lightning protection device is strapped to the cold
water pipe as well.

Yes, that's very true of rec.radio.amateur.etc and the various mailing
lists. Since substantial numbers of amateurs have gained access to the
Internet, many problems that have hung around for years have been
thrashed out and - if not settled - at least the essential points
identified.

But that doesn't apply to web publishing because it doesn't have the
same built-in opportunity for public discussion. Unfortunately many
people don't "wrestle with their material" - they just publish it.

the pathetic size of QEX makes it a poor buy. Those one or two good articles would hardly be ever noticed in QST. In fact QEX ANd national contest journal could all be put into QST. It would make the magazine more appealing. People seem to forget how great ham radio magazine was, it had good general technical information as well as good technical articles. Its failure was it did not have enough general articles like QST. This combo of technical accurate as well general articles would work. It wont happen since all these publications is a money making scam like the antenna handbook and the ARRL handbook. Full of misinformation and highly inaccurate material, it gets repeated year after year with same errors. This is from a organisation thats is supposed to be technically correct.

Have you seen the 'fad' of truckers tilting their 1/4 verticles forward at a 45 degree angle? As a broadcast engineer of over 13 years experience I thought this was the dumbest thing I ever saw. Well, guess what? I drive truck now (and make far more money BTW) and I tried the 'tilt' thing. It actually works!! Why??? I am thinking that it gets the high impedance end of the ant away from the trailer. It should work far worse in this tilted mode, but it works no less than 1/2 'S' unit better in most cases, and seems to enhance my range by perhaps 1 mile minimum. So, what goes??

No Problem,

D.C. headphones are simple. first, the ear piece. they are low impedance. 8 to 10 ohms typical. So, that part is easy as you have probably found.

Now the mike part. You need a source of 6 to 12 volts D.C. very noise free. Use a series resistor of perhaps 220 ohms and a cap of 100mfd or bigger to ground to create your noise free power supply. Now, all you need is a resistor to the 'hot' lead of the mike. I have found that 1k ohm works well. Then you will need an audio coupling cap into your 'original' mike circuit. 1uf to 10uf should work well for even the lowest impedance dynamic circuits. Some of the David Clarks have a small screw driver 'audio level' adjustment right on the mike. You may have to turn it down to avoid distortion in your tranceivers mike pre-amp circuit.

441. Calculate transistor amplifier input impedance?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-16 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <38812a12.86182663@news.online.no>
Source record: 64129

how is input impedance calculated for an inverting amplifier with shunt feedback?

Wish to use an amplifier consisting of 2x 2N2222 (BC238), the first is common emitter stage, with 100 ohm emitter resistor (no decoupling) and 4700 ohm collector load, the second stage is emitter follower and the feedback is 1/5.7 (47k from last emitter to first base, and 10k to ground)

it is supposed to be used for 1.5kHz meter amplifier in 136kHz measuring equipment, input voltage is 0.2V RMS

hpe to hear from you sn

And so what the hell is the 'IT' that I have missed???? I would
not have belived 'IT' would work. But i tried 'IT' and I tell you
there was an improvement that could be measured. Unlike the 'IT'
that 'Audio Pills' claim to be able to 'hear' with their calibrated
ears. I would have assumed (let me take the moment to make an ASS
of U and ME) that 'IT' would behave predictably. Like the 9 db loss
for incorrect circular polarization, or the 20 db loss for improper
H/V polarization. Tilting the antenna seems counter produtive.

Oh please, Oh please, if you know of, or in fact control this
mythical 'IT' that I have missed, please tell so that me and many
like me can elevate to your 'Elmerness' and good standing with
the wavelords of the ether.

Well, MC, I can't agree about the trade journals. While they are
valuable for keeping abreast of the latest technology (systems
engineering advances and new ICs), they're *really* light on practical
electronics and construction, and technical discussions are generally
non-specific, full of generalities and block diagrams of things they
wish would work, and glassy-eyed promises about upcoming products that
are usually unavailable to hobbyists and experimenters.

I prefer schematics, pictures, measurements, explanations, and
practical guidelines. As a hobbyist, I look to magazines like
CommQuart, QST, QEX, SPRAT, and the like, and Internet web sites. As
a professional, I look to data sheets and application notes (usually,
by the way, also available on the web)

>the feedback is 1/5.7 (47k from last emitter to first base, and 10k to
>ground)

One way to think about this: if you force the input 1 millivolt higher, what change in current happens at the input? For your case, the first stage gain must be pretty close to -4700/100 = -47. Assume the emitter follower stage has unity gain, so with a 1 millivolt input change, the output drops by 47 millivolts. The voltage divider to the base makes that look like 47mV/5.7 = 8.25 millivolts, at a source impedance of 10k in parallel with 47k which happens to be 8.25k in this case...that's just a coincidence. So the input current changed by 1.0 microamps for a 1.0 millivolt change, and that's 1.0kohms. For completeness, you must also factor in the input stage base input resistance, which must be about 100 ohms times the transistor beta, or maybe 10 to 20 kohms. So the net input impedance must be a bit below 1kohms.

Cheers,
Tom

>is... please excuse my ignorance.

Apparently the metric system is not well known on your side of the
Pond.

Millimeter waves 1 .. 10 mm = 300 .. 30 GHz = EHF
Centimeter waves 1 .. 10 cm = 30 .. 3 GHz = SHF
Decimeter waves 1 .. 10 dm = 3 .. 0.3 GHz = UHF
Meter waves 1 .. 10 m = 300 .. 20 MHz = VHF
Decameter waves 10 .. 100 m = 30 .. 3 MHz = HF
Hectometer waves 100 .. 1 km = 3 .. 0.3 MHz = MF
Kilometer waves 1 .. 10 km = 300 .. 30 kHz = LF

Yes, I have to admit that recently I have only seen references to
kilometer, centimeter and millimeter waves. Hectometer band/waves has
been used in some languages to refer to the medium wave broadcast
band.

Hope this helps.

isnt it strange -
one very often see newcomers who want to build complex rigs while they
are usually expected to do something simple

perhaps it has something to do with the age....where the newcomers
above 60 need something simple, hi

Personally, when I was at an age of 14 I found most of the newcomer's
circuits to be rather boreing, perhaps I started too soon.....

I have also learnt a few french words since then

From: Kevin Mitchell <sparc@ihug.co.nz>
Message-ID: <85t77i$2sm$1@news.ihug.co.nz>
Source record: 64059

Hi All,

I am looking for any mods, information etc for the Dragon SS-485+ 10meter tranceiver.
I have one, but have found that it has a few short comings in it, ie. you can not scan while in memory mode, depending on what step you are in, it will only scan that 10's portion. What I mean is that if you set the step to 10khx, and the freq is set to say 28.500, it will get to 28.590 and then go back to 29.500 and start again. Sometimes a good idea, but it should carry on up, 28.590, 29.600, 29.610 etc.

Anyone got any ideas.

Regards

Kevin, ZL1UDD.

Did this happen on all TV channels ? Was the picture affected ?

If the picture is not affected and the problem occurs on all channels,
then this is an audio break through directly into the audio system of
the TV.

Are there external speakers connected to the TV ? If so, disconnect
the external speaker wires from the TV and the interference is not
heard on the internal speaker, the problem is audio break through from
the speaker cables. If there are no external speakers, then most
likely, the interference comes through the power line and wrapping the
power cord around a ferrite bar should reduce that interference.

Make that decameter :-).

The real reason is that nobody is talking about wavelengths anymore
when referring to a specific emission, except radio astronomers (and
radio amateurs :-). Thus, it does not make much sense to talk about
wavelength bands.

>In the same way, 100 mm is "in", while 10 cm is "out".

The cm is still quite common over here and so is hectopascals (to give
the same numeric value as millibars, used only in weather reports),
but apart from that, power of 1000 prefixes are used also here in
Finland.

Anyway, the original poster apparently asked about a 1 kW HF
amplifier, but no-one have commented on that.

467. Help with AC noise

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-17 00:00:00 UTC
From: kd8gt <bubba@somewhere.com>
Message-ID: <fgd68sssgfasl2cegckl0spupr4f6if4jf@4ax.com>
Source record: 64070

My computer monitor is very dirty, producing a buzzing ac noise about 10 kcs wide at every 50 kcs on ALL the HF bands on all my hf receivers. It doesn't effect VHF. I doesn't matter if a rig is next to it or across the room, it's the same. I have isolated it to the monitor, turning it off, eliminates the noise so it's not the computer. Turning monitor off is not a option as I want to use it for logging. Rigs are grounded good to a earth ground. Any suggestions, short of buying different monitor? By the way it's not a cheap monitor, 400 dollar range 17". Suggestions please?

Source record: 64071

A smaller monitor might be cleaner, since the high voltage would be less. You can try ferrite cores on the cables, line the case with metal and ground it, add a power line filter, and so on. It's often a losing battle. And if it's a new monitor you can return it for warranty as they are required to be fairly clean by FCC. Try connecting the computer ground to the rig ground.

You might have to buy a different monitor.

many thanks, and gain is 5.7 when the amplifier is fed from high
impedance (without taking in account the loss one has), and has higher
gain the lower the generator's impedance is? Gain limit is somewhat
lower than 47.

Is it a similar way to calculate the output impedance? Output voltage
is 6V over 2200 ohm. I would say that output impedance without the
feedback is (4700+rb)/hfe. hfe for BC238 is at least 200, and rb is
supposed to be 1k, so I believe it is 27 ohm - without feedback.

I have a guess. I've never sat down to try to analyze it, and my antenna
knowledge probably isn't up to it anyway. But it seems to me that an
antenna tilted at a 45-degree angle off vertical would present 0.707
as much energy to a vertical antenna as another vertical would. And I'd
say with some certainty that anything you could do to get the antenna
to stop being parallel with a nearby large conducting surface would be
an improvement of some sort. My guess would be that the loss would be
offset by the benefit of getting non-parallel to the trailer.

I had to check an issue of Communications Quarterly to see if this guy
was really referring to Rick Littlefield, who's written quite a few
interesting articles for the ham magazines over the years. K1BQT is
is indeed Rick's callsign, so I have serious doubts that there is
any legitimacy to this post. And I just did some searching on dejanews,
and Fractenna started the same thread in rec.radio.amateur.antenna (too
often someone posts to many groups based on how important they think
the post is, and too often they are wrong. And if there is anything
worse than cross-posting, its posting the same message to multiple newsgroups
one at a time) and Rick there have been more suspicious responses over
there, where Fractenna is obviously a frequent poster. Rick even
answered in that thread, and I think people might want to go over
there and read his message before believing Fractenna's message.

I did browse through a few of previous messages to "Fractenna" and
did see the reference to 'Chips Final Act' and it seemed to be in a joking
tone, and it sure didn't read as a death threat.

Being a famous author doesn't make someone perfect, but I suspect
this post is an attempt to damage K1BQT, indeed some damage may have
already been done, rather than a real situation.

Source record: 64079

www.ebay.com item 238999733

FS: wonderbar Radio for a '57 Chevrolet Belair, 210 and all related
models. It is in near-Mint condition! It has very recently been
totally restored electronically. All new circuits, capacitors,
tubes and totally checked overy by professional radio repairman.
The chrome is in very excellent condition - extremely shiny!
Everything works on this very rare radio.
All metal is in
really great condition. No rust. All checked out and ready to play
in your classic car. ..
I can send along the receipts I have for all work done. It is still in
original box from repairman. Due to the age it i sold AS IS. However, if
it fails to work when
installed it can be returned to the repairman to be fixed at no
cost except for parts.
Chrome is truly excellent but it does have a couple of tiny 'specs'
on the knobs. No fading at all on the chrome. Very shiny. Black
buttons are mint. Needs nothing! Tops of tubes have a nice shiny
chrome on the glass. These were not chrome plated but are a natural
part of many tubes. Lettering on "Wonderbar" switch is perfect.

Attached is the National semiconductor circuit suggestion for a 1.5-30V constant current/constant voltage power supply. I like the circuit as a possible workbenchbench power supply. Two queries however: 1) the LM301A op amp shows 6 volt input plus Vcc. I asume the Vcc is 15volt, why the difference, shouldn't it be -15 volt and not 6v as shown?

2) the R8 voltage adjust potentiometer: any way of determining what its value should be?

Your help would be appreciated

I have a neighbor (a fellow ham friend) 2 houses away that has problems with my 40 meter CW transmissions. Three times he has had the cable company come over to is house to "fix" his problem. He also
mentions that one of the cable station's audio is at the same frequency as the air distress band.

NatSemi and others list the Vadj pot at 5K. This has always worked
for me, and higher values have worked but only with the 0 - 5K range
effective. If you have a well-stocked junk box, you might consider
using a 10-turn pot (up to 50K would give you at least one turn range)
or experimenting with swapping the legs on both audio taper and linear
taper pots to give the most control in your voltage range of choice.

And there is no reason whatsoever that prevents you from building
several variable supplies in the same box using the same transformer
as long as you consider what your total load is likely to be, and size
the transformer accordingly. I've been lucky enough to always have
big iron handy...

488. Re: mobile verticle ant question (opinions?)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-18 00:00:00 UTC
From: Jim <jdport@concentric.net>
Message-ID: <388483FE.3BC33686@concentric.net>
Source record: 63947

I've noticed the forward-tilt of the Trucker CB'ers for some time, and have thought that it might have been so the antenna(s) would tilt toward vertical under highway speeds. Getting the antennas spaced a bit further from the "box" may well improve performance toward the REAR, which has always been weak for truckers compared to range toward the front of the vehicle.
Heh. Antennas have always been something that don't always "obey the rules"... if it works, fine.

Yaesu had them the last time I checked about a year ago but the price was
something like $140.
This maybe more than you want to spend or they may not have any left.
The only other thing you can do is find a parts radio. Good luck.

Hi Jan-Martin,

OK, yes, the gain would be somewhat less than 47 with zero impedance source. I should have said that the effective emitter resistance is 100 ohms plus about 26mV/i, where i is the emitter DC current, so if it's 1mA, that makes the open loop gain more like 4700/126. And of course, the emitter follower doesn't have perfectly unity gain, either, and will reflect a load back to the first stage collector, too, all of which lowers the gain further. It all depends how accurate you need to get! (Op amps, with high open loop gain, reasonably low output resistance, and high input resistance, make things very easy to calculate, usually.)

The output impedance will be reduced by the feedback loop gain. In figuring that, you must figure a voltage divider of 47k feeding into (10k in parallel with your source resistance). So if the source resistance of the input signal is zero, then there is no reduction because of feedback--you have shorted out the feedback with the zero-impedance source. But if the source resistance is, say, 10k, then the feedback ratio is 5k/(47k+5k) = 0.096. (5k = source impedance in parallel with the circuit's 10k.) The feedback loop gain is that, multiplied by the open loop voltage gain, say 45, for a total loop gain = 4.3. Output impedance will be about the open loop output impedance divided by the loop gain plus 1, so about 27 ohms/5.3 or about 5 ohms. Of course, as you note the hfe is an "about" number, so don't expect the output impedance to be super well defined.

Also, not to be forgotten: negative feedback applied as a voltage effectively in series with the input raises the input impedance; applied effectively as a current lowers the input impedance. Negative feedback derived from the output voltage lowers the output impedance; negative feedback derived from the output current raises the output impedance.

Cheers,
Tom

> as shown?

I guess you posted the .gif in another message... The .gif you posted isn't the same as in my National data book, nor quite the same as in the data sheet I downloaded a few days ago. The "6V" should be "-6V" (with respect to ground). If you made it -15, you'd exceed the power supply rating of the op amp, at high outputs. You didn't ask where pin 7 goes...one of my schematics shows it going to the output voltage, though that then assumes an op amp with input common mode range that goes all the way to the + supply and even slightly beyond, which I don't think the LM301A will do! There are some modern op amps that can do it. Power supply for the op amp is a bit of a problem if you want really wide range. You _could_ use a BB OPA604, which can take 44V or so total supply. I'd go with some pre-regulation, like +32V and -6, with an OPA604...

Hi;

Repair shops / tube audio gurus / radio buffs take a look!

One lot of tube shields for the 9 pin miniature tubes (12ax7,
12au7...etc) these are the twist-lock spring-loaded type used in
radio and tube audio gear.

There are over 300 in the lot.

Stock up now!

Don't miss out on this one! Only 22 hours left to bid!

The national LM 350 is a regulator chip that will produce 3 amps when mounted on a heat sink. Output voltage is 1.5 - 35 volts. If you can find in the handbook a circuit for the LM 317, just follow that but substitute the 350. If you can get the national power supply handbook you will find all of that information. I am using this regulator in my "bench supply". I use it for everything. Impossible to see hum or noise on my tektronix 465 scope.

good luck

Hi,
I'm just wondering exactly how to phase 2 and possibly 4
Helix (helical) antennas properly, there's not much info about this out
on the net.
Thanx

Dear om
if you can help me I`ll be happy :)

I have a Transceiver (Kenwood TS-140S)
But it is not work now

SYMPTOMS :

First time : good receive but audible alarm " UNLOCK "
with morse code time to time .

Now : - open display firs time (forexample 14.000.00)
- after opened display (like . . . . .)
- not receive also not any sound or hiss
- not transmit
- alarm " UNLOCK " with morse code repeatly .
- when I rotate Tuning knob display is open
like 14.230.00 but again . . . . . .after 1 second.

I measured 3.2V on back-up lithium battery .

515. Hall-effect sensors?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-19 00:00:00 UTC
From: mcalhoun@ksu.edu
Message-ID: <864tdj$jbv@unix1.cc.ksu.edu>
Source record: 63968

The current Radio Shack catalog lists 10-15 Hall-effect sensors, but my
local store doesn't carry any in stock, and I don't know enough about
Hall-effect sensors to know what to order.

What I'd like to do is make a "radiation sensor" which senses "radiation"
simulated by a magnetic field, for use in hazmat drills. I'd like to be
able to scatter "sand" mixed with some tiny bits of magnets and then have
trainees detect the "bad stuff" as if they were using a radiation monitor.

Assuming a Hall-effect sensor acts either as
* a variable voltage source,
* a variable current source, or
* a variable resistor,
I should be able to convert the output to something which would
register on an analog meter or DVM or ....

Does anyone know enough about the kinds of Hall-effect sensors that
Radio Shack (or anyone else) sells to suggest which I might use?

519. Re: Calculate transistor amplifier input impedance?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-19 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <3884f82b.335589369@news.online.no>
Source record: 63972

tnx to all for valuable information!
I'll keep it, it seemed first that a two stage amplifier with +12V
supply was easy for dead-bug mounting,
but I could need some more gain, and a 741 will solve my needs very
well, so I will use this device (with 12V supply),
it is good for the purpose, to amplify a 1.5kHz tone from selective
voltmeter to drive a voltage doubler and a 40�A meter with sufficient
hold time for good reading on 136kHz morse signals

the problem with the Wandel & Goltermann selective voltmeters I have
studied the circuit diagrams for (quite a lot) have a constant current
source for the rectifier/voltage doubler and have no excess output
voltage to the meter circuit. Because of the hi-z ciircuit feeding the
meter circuit it must have a low time constant to read fast enough

The amplifier is connected to the so-called "IF-out (1.5kHz) for
selective operation", level is 0.2V RMS in 600 ohm, it is amplified to
2.5V with few hundred ohm or less output impedance and fed to a simple
2x1N270 detector, I don't care to use op-amp for this purpose, or
build sample and hold detector (See: G3SEK's "VHF/UHF dx book").

One project LB8X and discussed for some time is an antenna analyzer,
see G3LDO's book, you build a simple circuit and take 5 measures from
simple diodedetectors, calculate for the failure from the different
detectors on different RF voltages, and calculate from a formula
(quite impressive algoritm) to present a result on digital meter or
convert to analog reading, presenting impedance in R+jX or Z<angle

make it portable with remote control to the PC, store the results from
different antenna tuning for later studies

it is also some easier way, using ATMEL AT89/90 series flash
microcontroller, you can program the device using simple basic, and
correct wrong functions
I've just received a starter kit

My interest covers most amateur radio bands from 136kHz to 24GHz

Hello Myron

I think I understand what you are trying to simulate. All the Hall sensors I have seen are for sensing from sevral hundred to a few thousand Gauss.

What you need is an instrument that has a sensitivity of a few milli-gauss. Magnetometers that sense the Earths magnetic field would be hard pressed to sense a change to the Earths magnetic field by a few metal filings spread around. The earths field varies from aproximately 600 to 800 milli-gauss depending location.

I'm afraid you are going to have to find another method of simulation for your training.

Right you are Steve! I once had a "new" Viking Valiant transmitter that exhibitted the "downward modulation" phenonenon so prevelant in those days. I had an old power supply laying around and re-wired the Valiant to use THAT old supply for the Modulators. VIOLA! No more downward movement of the P.A. plate current! I guess the Valiant supply was just not "herky" enough to keep stable supply voltage to those three 6146's when the Modulator's also were dragging power off, at a voice rate. But I loved that old rig, and if I had it today, I'd work 10 meter AM, just to watch the Mercury Vapors flash!

you needen't jump over the river to find water .....could try this kit
using inexpensive components, telephone number to SM6DJH is
+46-523-30015

In SM-QTC nr 12/99 and possibly nr 1/00 SM6DJH describes a rather
interesting high performance single band CW transceiver with ladder
type 5MHz xtal filter.
He underline the importance of using readily available components, the
transistor types have been available for almost 40 years and may still
be available in one or another version for many years to come, such it
is not possible to say about integrated circuits.
Semiconductors are BF199, BD135 (or BD137, BD139), BC547B (TUN) BF245B
and BC557B (TUP). The receiver even has AGC, some of it is on another
IF =1MHz using a 6MHz ceramic element in the oscillator. Only few
coils in RX and TX must be wound, in large extent is used fixed value
coils with values like 0 33, 1 H, 2 2, 10 H etc, it is therefore
easier to tune it up without too much complications.

RF output is 5W on 80m, 4W on 40m and 1.7 on 20m but using BFW16A or
2N4427 as driver stage the output may be increased to 3.2W

no email address is mentioned, only phone number

19 January 2000

Below is a summary of the threats to harm made by Rick Littlefield. Those who have expressed an interest can now see them directly and in context of time and subject.

I am grateful for the help from others in getting Mr. Littlefield to diffuse his focus on my harm.

Nathan 'Chip' Cohen
N1IR

The following is a summary of the threats to harm Dr. Nathan Cohen by Frederick Littlefield.

Pointing out the threats publicly has appeared to have had a positive effect, in that it has made Mr. Littlefield aware of the severity of his statements, although he is strongly in denial.

Dr. Cohen has decided to go to local and federal law enforcement should Mr. Littlefield make any more statements threatening him. He has also publicly suggested, although Mr. Littlefield has not complied, that Dr. Cohen and Mr. Littlefield have no interaction whatsoever, including responses to posts made by the other. This summary, when posted on USENET, is the last one made regarding Mr. Littlefield on USENET by Dr. Cohen.

SUMMARY OF THREATENING COMMENTS

In allusions to Nathan Cohen, Frederick Littlefield made the following statements: Both come from dialogue publicly posted on USENET between Thomas Rauch and Frederick Littlefield. Both are radio amateurs with callsigns W8JI and K1BQT respectively.

****
Re: Goodbye AOL
15 Jan 2000

< Can K1BQT help?>

"Yes I can, Tom. I know an established North End family with a unique approach for resolving libel claims for out-of-town clients. It's not cheap, but it's faster than the courtsâ€¦"

73

Rick K1BQT

****

AND

****
RE: CFA (Cross Field Antenna)
15 Jan 2000

<What do you think?>

If Gypsy Rose Lee turned an indecent occupation into a glamorous art form, Chip has surely done the opposite for antenna design. Could CFA mean "Chip's Final Act?â€¦"

Rick K1BQT

****

Both statements -made the same day--clearly refer to efforts to harm Nathan Cohen. The first refers to a "family" living in a section of Boston with historical links to organized crime; this "family" "resolves" libel claims outside of the court system, for a hefty price. This is a threat against Dr. Cohen designed to prevent him from pursuing legal action for stopping long-term harassment by Thomas Rauch against Dr. Cohen.

The second statement clearly refers to a "final act". Dr. Cohen is a scientist with 33 years of antenna building who is one of the prominent researchers in the field.of antenna design. Mr. Littlefield is stating that there is a "final act" to an ongoing profession for Dr. Cohen. Dr. Cohen has never given any indication that his work in this field is anything but ongoing. Thus we are asked to contemplate a means by which Dr. Cohen is terminated

It is important to note that motivation for such is presented by Mr. Littlefield. He asserts that Dr. Cohen is responsible for the destruction of an occupational field of endeavor, for which Dr. Cohen is well known to the public, into an "indecent occupation".

On 18 January, in another public USENET post between the two, Frederick Littlefield again refers to the 'North End ' reference to Thomas Rauch, confirming the that the intent is to harm Dr. Cohen, in an allusion to the breaking of knees by a "North-End family". Notice the change in wording from "family" to the single "surgeon"-a perversion of the harming of people by breaking their knees-- after Dr. Cohen expressed public fear of harmful intent by Mr. Littlefield:

****
Re: Death Threats
18 Jan 2000

On the 15thâ€¦ I see that I offered to put YOU [Thomas Rauch] in touch with the services of a fictitious North-End Boston knee surgeon to help YOU resolve YOUR libel problemâ€¦.

Rick K1BQT

****
No info is proffered as to why a surgeon from a "North-End family" would be in any way involved in resolving a libel case. The suggestion is now presented that Dr. Cohen can be harmed by having his knees broken, thus indicative of harmful intent.

528. Identifying Belden cable help needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-19 00:00:00 UTC
From: Will White <kd7bfx@mindspring.com>
Message-ID: <38865AE0.38B0B169@mindspring.com>
Source record: 63981
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I have come by a large length of what appears to be Belden 2668 cable. I can't find that cable type in any of my catalogs or in the Belden on-line catalog. What I have appears little used, with gray PVC covering, about 0.5" in diameter, is terminated on both ends with 37-pin Centronics-type male connectors, and is marked thus: "Belden AWM STYLE 2668." Can anyone tell me what this cable is used for, and how much it costs (I probably want to sell it to someone who can use it)? The cable also has an inspection tag from what appears to be a vendor (Kertech in MA) that refers to "Part # LC37(7S)PP." Thanks.

529. Help! How do I test coax to see if it's damaged?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-19 00:00:00 UTC
From: ghopper@eskimo.com
Message-ID: <ghopper-1901001809380001@05-043.009.popsite.net>
Source record: 63982
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I have several lengths of coax (some RG-58, belden 8237, and RG 213) that have had uncertian histories. At least one of the lengths has spent several days under water (fresh and salt) however all of them are clean so visual inspection has not been conclusive. I'd like to find the bad ones since several of the lengths are reported to be fine and they are from 25 feet to almost 100 feet long.

I have a good watt meter (a bird 43), a good dummy load (to 1000 MHz) and HF and vhf rigs but nothing like a signal generator.

Any advice on this topic would be appreciated, even if it's just a reference to an article in QST or other publication.

Thanks.

Source record: 63984
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Grant,

If you terminate them with the appropriate coaxial connectors,
you can find the loss with your rig, wattmeter and dummy load.

Here is the procedure. Assume you have the proper Bird slugs
for your VHF radio.

1. Connect the VHF radio to your wattmeter and dummy load
with good, short pieces of coax. Record the power and check the
SWR; is should be close to 1:1.

2. Connect a piece of test coax between the radio and
wattmeter. Record the power, it shouild be lower.
Verify the SWR is still close to 1:1.

3. The loss in the coax is the power reading in step 1
minus the power reading in step 2.

4. Attenuation in db is db = 10 log x power in step 2/power in step 1

5. The attenuation of new coax in db per 100feet is given in the ARRL
Antenna handbook or in a Belden catolog or webpage.
According the the ARRL Antenna book, the loss
RG58 at 30 MHz is approx. 2.4 db per 100 ft
and at 148 Mhz is approx 6 db per 100 ft.

Compare your attenuation per 100 feet to the specs. Good coax should
be close to the specs.

Hope this helps.

Sounds like the stuff that we used to use for the LV controllers for stage lighting. The control console and the dimmer packs were set up with 27, 37,or 53 pin QC's, and the trusses where already pre-wired. all you had to do was get 220 to the trusses, and then daisy-chain the controller cables from the stage box to the trusses. A larger version of the control 'snake' was routed along with the audio snakes to front-of-house where it was QC'd to the lighting control console.

the small chunk I have here is silver-colored jacket with 34 pairs of 26-gauge solid core.

Message-ID: <Wgyh4.935$A45.59465@news.corecomm.net>
Source record: 63990

Hi, Don.

Your module is indeed a TRW device. It is specified as a 400 to 440 mHZ power module with 20 watts output at 12.5 VDC operation. Power gain is 20. Harmonic content is -40 dbc. In and out impedance is 50 ohms. It will withstand infinite VSWR. It also contains a pin by which you can control the gain.

Sounds to me like you got a winner there.

Sorry I don't have pin outs but if nobody can come up with this info, e-mail me and I will search through my stacks of paper and see If I can find it. :)

Source record: 63991

You need some kind of test equipment such as a bridge to measure that capacitor. There actually are many ways to do it but much depends on how important it is to you and what you have around the shack.

For example:
1. A capacitance meter (often part of a digital voltmeter)
2. A capacitance or impedance bridge
3. Known capacitors for comparison; you can, for instance, measure resonant frequency with the unknown in the circuit and then put in various known values and match the frequency
4. Similar to no. 3, but you don't need to match it, just measure and calculate by the difference in frequency using the usual formula

and so on....

But it does pay to understand the theory so you can devise a method based on common sense and the theory of electronics rather than getting someone to tell you how. You know the old saying, give a man a meal and you feed himi for a day - teach him to fish and you feed him for life.

The handbooks since 1995 have a circuit that does the same function as the IF-232. For the TS-940, you will also need a IF-10B which is a circuit board and EPROM that installs inside the radio. The IF-10B is very hard to find since they are no longer made. Used, expect to pay near new price ($80.00)for one.

Hopefully one of you ham radio people can help me out with this problem here,

I work for a security company in the NW Suburbs of Chicago..we have 5 cars that cover this 2 mi apartment complex area. We'd like to setup an MDT System within this 2 mile radius that'll allow the MDT's to communicate to each other & access a database. We can obtain 5 Motorola MDT 9100-11's no problem..I just don't know how to set them up to communicate with each other & access a central database.

If anyone knows how to setup an operation like this, we'd be willing to pay them a few hundred bucks to make this work. Email me at gkaiser@starnetinc.com if you can help me or provide me any information.

Thanks!

-Greg Kaiser

The formula is in the ARRL Handbook - if you know the area of the plates, the spacing and number of plates you can come pretty close to what a capacitance meter would tell you, of course, to find the impedance you have to know the frequency!

From: rick@vax.area.com
Message-ID: <867e1f$4vort$1@rn.area.com>
Source record: 64009

I would like to do some remote control work over phone lines and one idea I am looking at is using the DTMF pad on the phone to control a computer at the remote site. I need a little board that converts DTMF tones to RS-232, or perhaps software for a sound card that detects the tones (preferably the hardware solution.) I know that 2 meter repeaters can be commanded with DTMF tones, but I don't know a thing about how this is implemented. Another possibility is to connect the tones to the computer via the parallel port.

Once I get the tones detected in the computer, I need to send out RS232 commands to the radio. I would be interested to know if there is some real idiot proof software (like a BASIC interpreter) that can handle this simple task on a grut PC. The problem I've had with other compilers is in the I/O commands. Frequently, the documentation for a BASIC interpreter will say I/O is machine dependent or refer you to documentation for the I/O hardware. Another issue is setting of IRQ's DMA etc. I would like this to be transparent to me as a programmer. (Actually I'm not a programmer, I'm a hardware guy, that's why this needs to be idiot proof).

Has anyone played with using USB as an interface? That would be another possibility.

557. Search for info about tube radios

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-20 00:00:00 UTC
From: Allmaier Hannes <allmaier@sbox.tu-graz.ac.at>
Message-ID: <38873807.9E713A9C@sbox.tu-graz.ac.at>
Source record: 64010

Hello!

I'm want to build a radio working with tubes. I thought it should be possible to get a simple cicuit somewhere for a simple little radio. It need not to be a powerful one, because I plan to connect it to my amplifier (so the radio should only receive and amplify the radio signals, my amp should do the rest).

I'm completly new to this subject and hope that there're some guys out there who can help me.

THANXX YA

558. Cross needle meter source....again

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-20 00:00:00 UTC
From: Roger Leone <arleone@inreach.com>
Message-ID: <j6Hh4.163$6L1.4958@news.inreach.com>
Source record: 64011

Because my e-mail software doesn't show previous threads on this, perhaps this is repetitious.

The cross needle meters like the ones MFJ uses in their tuners, can be bought from MFJ! I replaced one in a friend's tuner. The cost was something over $20 as I recall, but we wanted the tuner to work and considered that a necessary expense. I called MFJ and they were happy to send me the meter....

For the typical ham who likes to scrounge parts, that may seen a bit high for a meter, but the retail price of meters is always high.

Hi;

One lot of (250) 9 pin miniature tube shields. These are for the
12AX7, 12AU7 ...etc tubes. Current bid is only $10.50 on the entire
lot.

I have seen these go for over $3.00 each on the net.

This is the last lot I will have up. I doubt you will ever find a deal
like this again!

You may have thought of this already, but:

See if you can borrow a SWR measuring device like an Autek RF-5 or the
MFJ equivalent. These contain a variable-frequency oscillator that
can be adjusted over a wide frequency range plus a frequency counter.
Attach a bit of wire to the output and you have a low-power transmitter,
without building anything.

Source record: 64026

I just went through this aligning a Hamtronics R139 WeSAT receiver kit using a MFJ 259B Antenna Analyser. The kit went together fast. All 5 channels worked and could hear the 259 as I swept the signal across a given channel. As the receiver alignment improved, I needed to attenuate the signal. I placed the 259 further and further down the hall on the floor.

What you really need (and me too) is a stable signal generator with an attenuator for reducing the signal output. The 259 was adequate, but the frequency was not as stable as it should be to do a proper job.

Good luck with your receiver.

Cheers, Greg

Binary attachments, which don't belong in non-binary newsgroups, are
frequently chopped off by large-scale news servers before the article
they were attached to is forwarded to other news servers. It might even
be that Larry's own system chopped it off before posting his article.

If you can't find one chip that will do it, the easiest way would be to connect the four data lines from a DTMF decoder IC to four of the data lines on a UART. The DTMF decoder should have a line that pulses when good data is received; connect this to the strobe on the UART transmitter. A level converter on the UART output and you should be all set. You'll want to try to get an older UART that has lots of pins and can be programmed with fixed connections; the newer ones are generally designed to be interfaced to a microprocessor and it can be hard to set the parameters easily. The one I used is no longer made - by a company that no longer exists... :-/ If you're looking for more detail let me know and I"ll try to find my data sheets.

Using these coax lengths, hook your exciter to the dummy load with an
swr meter in series and see what you have. Should be flat at any
frequency.

The SWR will not really tell much. The swr could be very low and the
cable could be very lossy. This is especially true of the cable that
was under water.

With the equipment at hand, hook the wattmeter to the dummy load and
measure the power of the highest frequency transmitter. Then hook the
cable to be tested to the transmitter, then the watt meter then the
dummy load. The differance will give the loss of the cable. There are
tables that tell how much loss the cables should have at the frequency
under test.

Considering the frequency, a signal generator is far more appropriate
than a transmitter.

Unless the receiver is completely destroyed, the problem will be
getting a weak enough signal, not a strong enough signal.

Just for Info sake, most of the semiconductor manufacturers have been working diligently to provide online access to data sheets and Spice models. (web pages are a whole lot cheaper than data books). They generally concentrate on "web-ifying" their current product line first, then work backwards from there. There has been an amazing increase in the amount of info available online in just the past year.

597. Stacking Pwr Supplies?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-22 00:00:00 UTC
From: kg4fet@aol.com
Message-ID: <20000122103152.03575.00000934@ng-cf1.aol.com>
Source record: 63904

I need to stack 2 pwr supplies to supply my FT 100 with the proper current. My AIM 20 is getting to hot for my tastes. I get full out of the radio but the supply is way to hot if I do any rag chewing. I put a fan on it and that seems to help but I would like to take it easier on it. Here is the question. Can I hook the second supply directly to the the AIM's output or should I use a bus strip? The second supply is a Johnson Power 15 amp rated supply used for a Johnson business band base radio. The output voltage is the same on on both (13.98+/-.03 volts). There is not a switch on the Johnson pwr supply to turn it off, but that can be fixed.
Any Help would be appreciated,
Sandor KG4FET

Sandor, you shouldn't parallel power supplies. There will be no way they will share the current; the one with the highest output will take nearly all the load.

Further, you shouldn't operate your radio at 13.8 Volts. That stresses it too much. Set it for 12.5 Volts.

If you want to parallel power supplies there are ways but it's not trivial. One way is to put a small resistor in series with each supply. That way, when one draws current its output will drop a bit and the other will share some. But that will spoil regulation, as well as throw away power in the resistors.

You would be better advised to build or buy a larger power supply. Or get into the ones you have and modify them to share; that's more difficult. Or, finally, put a fan on the one you are using to keep it cooler.

Connecting power supplies in parallel can be tricky. The
load current may not be divide equally, especially if the
supplies are not identical. It is also possible that one
supply could be damaged during startup when one comes
on before the other. Unless you have a thorough understanding
of power supply design and the designs of your specific
supplies, safest thing is to just use one supply which can
handle the entire job.

I know that you can pull crystal oscilators +/-50ppm.

Can you pull SAW oscilators?

If so, how?

I'm looking at building a very simple one transistor transmitter for finding lost RC aircaft.

I have a schematic for a one transistor SAW resonator on 433.92 Mhz. It uses a panasonic SAW device. I'd like to induce a steady 1Khz FM tone so that it can be tracked with a cheap scanner, or 70cm HT.

That's interesting. I know that binaries can be cancelled, but didn't know
that binary attachments might be merely chopped off. I've always assumed
that
when I see a message saying a binary is attached, and there's no binary,
that the sender had goofed.

Too bad about all the ads in rec.radio.amateur.homebrew They do seem
to be on an increase, and as expected, they don't stop at items specifically
related to building radio equipment, not that those are particularly
on topic in a discussion newsgroup.

Yes, the LM301A has a common mode input range up to the positive
supply voltage. The common biFET op amps (TL081) do too.

Note, there is an unfortunate problem with this type of power
supply... when the line voltage is turned off, the output voltage
tends to rise quite a bit while the filter cap discharges. Be sure to
check for this behavior before connecting anything that might be
damaged by it.

While one should not parallel power supplies unless they are designed
that way, most ham radios are designed for 13.8 volts. That is a
nominal voltage for most vehicles. The battery is about 12.6 but to
charge them you need a higher voltage.

Others have responded well to your query about (generally not) paralleling
power supplies.

But no one questioned WHY your FT-100 is overloading a (presumably) 20-amp
power supply. Even if the "20" is "max for a very short while", unless
your "AMP 20" is really unusual, it ought to supply something like 13-15
amps practically "forever". I've never owned an FT-100, but guessing
it to be rated at about 250 watts PEP, or about 125 watts DC, it ought
to need about 10 amps for the final plus a couple or three for the other
circuitry. Unless you have a speech processor driving it like mad, or
unless your "rag chewing" is actually RTTY, I'm surprised that your
power supply can't handle that demand.

The why is efficiency. Many transistor circuits do good to get around 50 % . I have a FT 757 that is a nominal 100 watt output rig. It will put out more than that on 80 meters, almost 150 watts without any problems. On 10 meters it just does make 100 watts . That is into a dummy load and Bird meter. The book calls for 19 amps of current at full load. I will assume that is only at 100 watts out.

The 10 amps you mention is only good if the transmitter is 100% efficient.

Many of the power supplies will put out the rated current with very little voltage drop, but the components seem not to be rated for continuous current. Several of the supplies I have tried will put out the rated current but if they are called to do it for a long time it is best to derate them. Some need it more than others. Some have a time limit on them as to how long you can draw the higher currents.

Hi All,

I have an opportunity to purchase a Singer CSM-1 Service Monitor. Looks like it may be a useful tool but there is no manual. Anybody have a manual that they would like to part with or offer up to allow me to make a copy? Anybody that has experience with the CSM-1and can provide me some information on it I would appreciate it.

As always, thanks for the help!

Rob

Source record: 64043

It's somewhat painful to simulate an entire PLL with SPICE,
so many people will simulate the circuit blocks individually
and then analyze the full loop behavior with a mathematical
model. I suspect that a SPICE macromodel will be difficult
to find.

There's a book you might want to check out:

The Design of CMOS Radio-Frequency Integrated Circuits by
Thomas H. Lee. This book has an excellent chapter on PLL's
with an extensive section on PLL design examples
that covers the 4046 PLL in great detail.

621. NEW Email List for finding Ham Auctions-Easy

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-23 00:00:00 UTC
From: Eugene Rippen <soundval@foothill.net>
Message-ID: <86gf68$5pj$1@ns2.foothill.net>
Source record: 63795

A LIST is now set up for the posting of "AUCTIONS" for
HAM related items (NOT TUBE era stuff). For our purposes,
"Auctions" mean items listed for sale without fixed prices.
Postings may be as simple as "$150 obo", or formal auction
terms, or the announcement of a URL at which there is an
auction (e.g. an eBay address, etc.).
"HAM" does NOT include audiophile gear, tubes or parts,
or CB stuff except linears actually tuned to only Ham Bands.

Not only are there notices of URL's of internet commercial
auctions, but also one can post their own auction. A
suggested form is even available for preparing one's own
auction and can be found at:
http://www.egroups.com/group/ham-auctions/7.html?

Subscribers have the choices of:
1. Receiving each email posted by each subscriber.
2. Receiving all emails once each day in one message.
3. Receiving a digest once each day of just the "subjects"
and "authors" of each message.
4. Receiving no emails. but allowing subscriber to go to
egroups.com and selecting this LIST
"ham-auctions@egroups.com" and then
selecting which messages to view by "subject"

To subscribe
SEND TO: ham-auctions-subscribe@egroups.com
Note: Plural "auctions" and "egroups"

RULES will be simple:
Post for HAM related items only, for which firm prices are
NOT stated. Not for tube era gear, another LIST
has been set up for that.
NO radio program tapes, magazine cut-out ads, CB stuff
(except linears tuned to Ham Bands), or tubes or
parts for the audiophile market.
Please refrain from claiming something is "rare" unless
certain almost anyone would consider it rare.
Post only once for each auction. (No followup messages)
PLAIN simple TEXT ONLY. (Not even a background color)
Use descriptive "Subject" headings.
Include closing dates where appropriate

To change the mode by which you receive messages
(Every message, all messages at once daily, all message headings only once
daily, or go to egroups.com and select messages to read)

GO TO: http://www.egroups.com
SELECT: "My Space" button
Then SELECT the group for which you wish to change
your mode of receiving messages.
SELECT: "Group Info" button on bar.
SELECT: "Modify Subscription" button at bottom page.
Then make the changes.
SELECT: "Apply Changes" button

FOR THE NEXT FEW DAYS (after 1/22/00) emails may
contain some advertising. That should end when egroups
receives my check, which has bneen mailed.

THIS MESSAGE MAY BE FREELY COPIED AND
REPOSTED in its entirety.

Eugene Rippen

According to the 10 GHz building block book published by WB6IGP, it's suggested the frequency is set plus or minus 30 MHz of 10.250 MHz. However undoubtedly it would be wise to coordinate the frequency scheme with the other local operators!

Paul Breed <Paul@rasdoc.com> wrote:
: I know that you can pull crystal oscilators +/-50ppm.

: Can you pull SAW oscilators?

Sure, any oscillator can be pulled. This is because the the oscillaor oscillates at the frequency where the phase shift around the loop that includes the feedback path is zero (or some multiple of 2*Pi radians). Induce a phase shift and the oscillator will react by changing frequency to restore the zero phase requirement, assuming it has enough excess gain to overcome any excess loss at that frequency.

: If so, how?

How far you can pull the oscillator depends on a number of inter-related factors including the _loaded_ Q of the resonator, the motional capacitance of the resonator (inversely related to the unload Q) and the excess gain. If you plotted the phase shift through the resonator vs. frequency it would look like __
\
\

The slope through resonance is proportional to the loaded Q of the resonator. So one way to pull it is with a varactor in series with an inductance which resonates the varactors capacitance at the operating frequency. This ciruit in series with the resonator can induce a positive or negative phase shift depending on whether your phase shifter looks net inductive or capacitive. The smaller the capacitance, the farther you can pull the device because the net reactance appears in series with the small motional capacitance of the resonator.

SAW's have lower Q than xtals so you should have an easier time of it. Don't forget to resonate the SAW's rather large (5 pF or so) IDT capacitance with appropriate inductors from any non-grounded SAW input pin to ground. I ususally use one of these inductors as the return for the varactor bias.

: I'm looking at building a very simple one transistor transmitter for
: finding lost RC aircaft.

: I have a schematic for a one transistor SAW resonator on 433.92 Mhz.
: It uses a panasonic SAW device. I'd like to induce a steady 1Khz FM
: tone so that it can be tracked with a cheap scanner, or 70cm HT.

You should have no trouble. The loaed Q of most SAW osc. at your frequency ends up being in the 1-2K region, giving a BW (assuming perfect centering) of saw 300 kHz. Remember though that its the deviation, not the rate in

FM which determines the depth of modulation.

One final question. Why bother with modualtion at all? Just crank down the squelch and look for the carrier.

Jeff

Most lamps in ham gear are rated for 'standard' automotive service, and will not last long at 13.8 Volts. And every piece of ham gear I have seen in the past several years works perfectly at 12.5 Volts. And lasts longer.

Check the specifications on your rig and you'll see that 12.5 Volts is well within the range, and does reduce stress greatly. Lamps are the most sensitive to this, but all those little regulators will run cooler and the finals will last longer too.

Maxim has a cool integrated 900Mhz MAX2622 VCO.
It runs from 855 to 881 Mhz in a microscopic package.
If I could find a divide by 2 prescaler that runs this fast it would
make
a really neat 70cm source.

I can find lots of divide by 8, but no divide by 2's.

Paul

>> unless your "rag chewing" is actually RTTY, I'm surprised that your
>> power supply can't handle that demand

My concern is this. At full out on 6 meters (100watts) the voltage drop from My main supply is tremendous. At full out voltage will drop from13.98 to 11.4. It is not a problem on the higher frequencies where the radio will do 50 watts(144) and 20 watts (440). With the supplies stacked I do get less voltage drop(14 down to 13.1). While checking it out today I noticed that the fans on the Ft-100 will reduce RPM's as well. This is a bad thing. SWR's on My 6 meter Dipole are low through the full 4 mgs of the 6 meter band (below 1.5). Radio calls for 20 amp constant and the AIM is 17 amp constant 20 surge. This would come close to explaining why I need to do something like this.
Thanks For all of the responces I have recieved and i look forward to continuing this thread.
Thanks Again
Sandor KG4FET

The NEC UPB581 is a divide by 2 that goes to over 2 GHZ and has
been available for over 15 years and costs less than a buck.
You can also use a Mot Eclinps flip flop to do this. Just connect
Q-bar to D and clock it.

Reduced prices and improved, much easier to read format.
http://www3.sympatico.ca/aquariusr/sale1.htm

A friend has set up a web site for me to sell off a 28 year accumulation
of electronic components including:
Coaxial Power switch,
RF power and other transistors, RF I.C.'s,
1N3712 Tunnel diodes,
1N5711 Schottky diodes,
Ceramic 455kHz and 10.7MHz filters,
Minicircuits mixers,
variable capacitors, both panel mount shaft type and trimmer
variable inductors and coil forms,
High voltage vacuum relays, rectifiers, resistors and capacitors,
Other capacitors including, Photoflash, polypropylenes, and tantulums,
Switches, such as foot switches and industrial limit (micro) switches,
Ferrites beads, toroids, large E cores, etc.
Transformers and inductors,
and lots, lots more.

Source record: 63939

Just go to the unofficial HAMCOMM web site of the author of the article for the VOLKS RTTY II. The URL is http://home.att.net/~k7szl/

Schematic, etc on the VOLKS RTTY II can be found there. K7SZL even sells kits.

Another approach is to build the original HAMCOMM interface and put a good RTTY audio filter in front if it. (Or a good SSB audio filter with adjustable highpass and lowpass filters). Audio filters are easy to pick up at HAMFESTS at a low prices. I like using the original HAMCOMM interface with an SSB audio filter in front of it since this combination can also be used NOT ONLY for RTTY and AMTOR BUT ALSO for SSTV (with mainly SSTV programs like EZSSTV and JVFAX).

If you want to use the VOLKS RTTY II mainly for PACTOR, you should really consider using a different modem -- the AN-93 modem which has a A/D chip for true hardware memory ARQ.

644. NEW Email List for finding boatanchor auctions - Easy

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-23 00:00:00 UTC
From: Eugene Rippen <soundval@foothill.net>
Message-ID: <86gf92$5ps$1@ns2.foothill.net>
Source record: 63943

NEW EMAIL LIST is now set up for the posting of
notices of "AUCTIONS" for tube era items..

Not only are there notices of URL's of internet commercial
auctions, but also one can post their own auction. A
suggested form is even available for preparing one's own
auction and can be found at:
http://www.egroups.com/group/boatanchor-auctions/8.html?

For "boatanchor" related items. For our purposes, "Auctions"
mean items listed for sale without fixed prices. Postings
may be as simple as "$150 obo", or formal auction terms,
or the announcement of a URL at which there is an auction
(e.g. an eBay address, etc.).
"Boatanchor" may include old tube type broadcast radio stuff,
but not recent audio gear, tubes or parts.

Subscribers have the choices of:
1. Receiving each email posted by each subscriber.
2. Receiving all emails once each day in one message.
3. Receiving a digest once each day of just the "subjects"
and "authors" of each message.
4. Receiving no emails. but allowing subscriber to go to
egroups.com and selecting this LIST
"boatanchor-auctions@egroups.com" and then
selecting which messages to view by "subject"

To subscribe to boatanchor auctions list
SEND boatanchor-auctions-subscribe@egroups.com
Note: Singular "boatanchor. Plural, "auctions' and
"egroups"

RULES will be simple:
Post for tube era related items only, for which firm prices are
NOT stated.
NO radio program tapes, magazine cut-out ads, CB stuff
(except linears tuned to Ham Bands), or tubes or
parts for the audiophile market.
Please refrain from claiming something is "rare" unless
certain almost anyone would consider it rare.
Post only once for each auction. (No followup messages)
PLAIN simple TEXT ONLY. (Not even a background color)
Use descriptive "Subject" headings.
Include closing dates where appropriate

FOR THE NEXT FEW DAYS (after 1/22/00) emails may
contain some advertising. That should end when egroups
receives my check, which has been mailed.

To change the mode by which you receive messages
(Every message, all messages at once daily, all message
headings only once daily, or go to egroups.com and select
messages to read)
GO TO: http://www.egroups.com
SELECT: "My Space" button
Then SELECT the group for which you wish to change
your mode of receiving messages.
SELECT: "Group Info" button on bar.
SELECT: "Modify Subscription" button at bottom page.
Then make the changes.
SELECT: "Apply Changes" button

THIS MESSAGE MAY BE FREELY COPIED AND
REPOSTED in its entirety.

Eugene Rippen

645. Standard 10GHz WBFM frequency and polarization?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-24 00:00:00 UTC
From: wbbblair@worldnet.att.net
Message-ID: <388bb4a0.18429269@netnews.worldnet.att.net>
Source record: 63800

I haven't been able to find confirmation of this in any one place,
but from putting all I've read together, am I correct in saying
that an unofficial standard for 10GHz WBFM activity in the US is
10.250/10.280GHz, 30MHz IF, vertical polarization? If not, are
there any other accepted standards?

Thanks,
Bill Blair
Cheyenne, WY

Judging from the list of addresses embedded in here, it looks to me like
somebody has a beef with PacBell.net and is trying to harrass their
support lines by filling them with porn complaints. I don't think
there's any real porn going on here. It almost looks like the jerk got
shut down for spamming & isn't willing to pay the penalty.

He'll probably wish he had when the police show up at his door.

Hello--
Most Teflon-insulated hookup wire goes through an extrusion process, in which the Teflon
gets squeezed onto the outside of the wire to form the insulation. This occurs at a
temperature high enough to oxidize untinned copper or vaporize standard tinning. However,
silver resists the high temperature just fine, and as a bonus decreases skin-effect losses
to some degree.

Teflon wire is wonderful to work with-- it won't turn to mush when you touch it with a soldering
iron; however, it's more difficult to strip and crushes more easily than PVC insulation.
Modern-day IPVC (irradiated PVC) wire insulation works reasonably well and won't
melt as readily as older PVC.

Hello--

While I'm not directly familiar with the Superior 650, I can offer a few general

comments re: older tube-type signal generators.

Many will do fine if you allow an extended warmup interval and monitor the output
frequency with a counter, but resettability without a counter can be poor due to dial
"stiction" and mechanical hysteresis.

Older signal generators tend to leak RF like a sieve due to inadequate shielding

(sometimes curable by installing more screws through the front panel and into the
cabinet) and due to radiation from the AC power line.

Which brings up a major problem: frequently, both sides of the AC line get bypassed
to chassis "ground"-- this puts the signal generator's cabinet at half of AC line voltage,
albeit current-limited by the bypass capacitor's impedance at 60 Hz. The leakage

can cause a tingle if you touch the chassis and a grounded piece of equipment, or
even zap semiconductors.

If one of the AC-line bypass caps is shorted (not uncommon with
older-style paper caps), you have a dangerous instrument that can deliver a lethal
shock.

You can sometimes improve AC-line radiation by installing a modern-design EMI/RFI
AC line filter of appropriate rating and a three-wire power cord that grounds the chassis.

You may have to replace the power-supply filter capacitors in an older signal generator.
Depending on their size, rating and availability, this can add $10-$20 to the repair tab.
On the plus side, if you're going to rebuild an older signal generator as a working instrument,
you can use less-expensive single-section electrolytics instead of a harder-to-find
multisection can.

If you're unfamiliar with vacuum-tube instruments, I recommend buying only those that include
a manual or at minimum, a schematic diagram. As you gain experience, you can take
more chances.

Many older signal generators use a microphone connector as an RF output connector;
I don't like these and replace 'em with a BNC connector.

Most older signal generators are harmonic-rich, and this can cause confusion if you
tune up on a harmonic (but here, a counter helps). Modulation can consist of AM or
FM (depending on features) or a simultaneous combination (on older, cheaper sig gens)<g>.

73,
Brad AA1IP

But didn't you have an article in QST back in 1968 about this? It had an
FET in the mixer, and probably the RF stage, and was intended to go ahead
of an
FM broadcast receiver for reception of the then fairly new 2M FM.

I've always wondered how well that scheme worked. Probably activity
was low enough that the wide bandwidth wasn't a problem, but since
the FM radio was designed for wideband FM, the surely the recovered audio
was low.

The ezsiest solution would be to retune an FM broadcast receiver, which
of course you saw articles about back then. But if the bandwidth problem
was okay back then, I doubt it won't be a problem now.

So you'd have to change the filter to a narrow one, and fix the discriminator
to deal with narrow deviation.

At that point, of course, it's easier to build something from scratch, though
a broadcast receiver would probably be the easiest source of an IC.

Thirty years or so ago, there seemed to be a move to single conversion
for FM reception, with an IF of 10.7MHz. But I remember reading about
problems getting enough recovered audio with that IF, since the narrow
deviation is a fairly small percentage of the center frequency. And it
sure seems like most of the junk I pull apart uses a double conversion
scheme, with 10.7Mhz and then 455KHz.

Motorola makes ICs that do that. Originally, they had ICs that took
10.7Mhz and converted it to 455KHz, where the IF and limiter worked,
and then the discriminator in some form. An example would be the MC3357,
and there were variations that had somewhat different features, though
I have no idea of their availability now.

More recently, Motorola also had double conversion FM receiver ICs intended
for narrow band FM. The MC3362 would be an example from a 1990 databook.
Motorola has fancier ones in recent years, Communications Quarterly ran
some articles from Motorola about them, but besides getting them in
small quantities, I think they are all surface mount.

These are probably better choices than something intended for FM broadcast reception, since they are intended for narrow deviation, and a lot of ICs used in consumer equipment isn't readily available.

However, with a little scrounging the ICs and filters are fairly available. As I've said before, superhet 49MHz walkie talkies from Radio Shack (and elsewhere) use something like the Motorola IC's I've mentioned above. I have some which are a bit older, and they use a traditiional front end ahead of the MC3357. By now, the things might use the double conversion ICs. One could either rework the front end for another band, bypass the front end and just use the IF strip, or put an external converter ahead of it.

The same ICs and filters show up in cordless telephones. The really cheap ones seem to use the ICs as a single conversion receiver going directly to 455KHz (and I think I saw one that used an odd IC), but I've picked up broken expensive ones for almost nothing that have Motorola ICs and the needed filters. Plus, you get two of the IF strips each time you rescue a broken
cordless phone. You'd have to extract the IF strip, and put a front end ahead of it.

I haven't looked inside, but probably some baby monitors use the same ICs. I can't quite picture them using superregen receivers.

Cell phones have similar IF strips, though the ones I've seen have a first IF above 30MHz. The older ones are becoming available cheap, since nobody once something so builky.

I don't know how Jim tested this filter for AM reception. It is 1.2 KHZ bandwidth filter not AM filter (FYI, Q5 is 0.5 KHZ CW filter, Q6 is 1.2 KHZ filter). It is O.K. for wide 850HZ Shift RTTY, not suitable even for SSB !

I suggest that on transmit that a minimum of 16 amps will be drawn, and that 20
amps is indeed possible with a 100 watt ssb rig. Remember that the rig is not
100% efficient in converting input current into RF, and that the usual
guestimate is about 50% efficient in the real world.

676. Re: Silver-plated Teflon wire.

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-25 00:00:00 UTC
From: "Barry L. Ornitz" <ornitz@NOSPAM.tricon.net>
Message-ID: <23aj4.160$_u6.16359@tw12.nn.bcandid.com>
Source record: 63831

Brad Thompson wrote in message +ADw-388D13DB.D46F0E49+AEA-valley.net+AD4-...

+AD4-Most Teflon-insulated hookup wire goes through an extrusion
+AD4-process, in which the Teflon gets squeezed onto the outside of
+AD4-the wire to form the insulation. This occurs at a temperature
+AD4-high enough to oxidize untinned copper or vaporize standard
+AD4-tinning. However, silver resists the high temperature just fine,
+AD4-and as a bonus decreases skin-effect losses to some degree.

Sorry Brad. I used to accept this explanation many years ago, but
it is is completely wrong. I discovered this when I worked in the
R+ACY-D facilities of W. L. Gore +ACY- Associates. Before the Gore-TEx
fabric was invented, their original product was PTFE insulated
wire (+ACo-). It is still a major product. They make PTFE wire that
is both tin and silver plated. And they can coat bare copper too.

PTFE insulation is usually used because of its excellent
dielectric properties (good from DC to beyond microwaves). Since
much of this wire goes into RF and high-speed digital
applications, silver plating the wire improves skin effect losses
in the wire. PTFE is great for high-speed digital signals because
as an insulation, it has about the lowest dielectric constant of
any plastic. In low end applications where only the chemical and
temperature resistance of PTFE is needed, silver plating is often
not used. The cost of silver plating is generally quite low
compared to the cost of the PTFE insulation and the precision
needed in applying it. While I cannot divulge particulars, Gore's
coating process operates at +ACI-comfortable+ACI- temperatures, not high
ones. However there can be a sintering process after extrusion to
achieve certain physical properties that is performed at high
temperatures.

73, Barry L. Ornitz WA4VZQ ornitzNO+AEA-SPAMtricon.net

(+ACo-) Gore was quite ahead of his time. While at DuPont,he
discovered how well PTFE was as a wire insulation. He wanted to
produce ribbon cables for early computers using the technology
because with a lower dielectric constant insulation, propagation
speed in the wires was reduced. Of course, this was in the early
1950's and computers were not very high-speed at all - and
certainly not limited in speed by cables. DuPont was not
interested so he formed his own company. Today, Gore is the
world's biggest consumer of PTFE resin. They make wire and
cables, the Gore-Tex fabric, medical products, gaskets, and
filtration products.

> modulator's plate milliameter?
>
> thanks again for any comments/info
>
> 73
>
> reply to: jwgbee@hotmail.com

Because, half the time, the modulator's power is actually subtracting
from the carrier wave. With a very small or no modulation signal,
the modulator (which is probably running class AB) won't draw much
power. But the RF Amp is still putting out carrier. So when you drive
the modulator, it draws power, which you read on your meter, but the
average power of the RF amp, even though it's modulated, doesn't
change, because half of the modulator power is going into the "valleys"
-
half the time it's "bucking," and the other half, "boosting."
So it averages out to the same power as a bare carrier.

Cheers!
Rich

I have a very nice Heathbuilt O-scope that has been giving me fits lately. I am the third owner of this thing, and its in near mint condition. The inside is very clean and all wireing seems to be in order from what I can see. I get no output to the CRT at all, however. I have replaced all the vaccuum tubes in the thing and when the unit is turned on, they all light up just fine. I am beginning to suspect that I may very well have a bad CRT, which I am sure is very difficult to find. Any suggestions before I go on the Quest for the Holy Grail in finding a very expensive and probably no longer manufactured part that I have no part numbers on?

I don't know about silver oxide, but the blackish stuff you find on
silver is usually silver sulfide. Silver sulfide has a resistivity of
1.5 to 2.0 X 10^-3 ohm-m, or about 100,000 times greater than silver.

There's a nice eBay price guide for Tek scopes at:

http://www.reprise.com/host/tektronix/reference/scope_prices.asp

Check it out, you might be surprised how cheap a lab-grade analog scope
is these days. You might be able to buy a 453 or two for what it'll
cost (in terms of time and aggravation) to get the Heathkit running
reliably.

To paraphrase MacArthur:" Old Scopes Never Die, They go to EBay"

The insides of a scope is something to be respected. You have to make sure there is no HV (unless you want to be sitting across the room on your fanny) and the CRT's, while not "fragile" like Bacarat Crystal, can be easily broken and fine shards of glass will get everywhere. It may be the HV - but you'll need an HV probe for your DVM.

When you consider the price of a manual, HV probe, possibility of purchasing a new CRT, it could very well be less expensive to buy a TEK453 as one correspondent suggests - somewhat of a boat anchor of a scope, but it does not use a proprietary IC's. I have one and the trace is just fine. Also, the ancient TEK545's are almost giveaway items these days - maybe $50 with a CA plugin. The only problem I've had with the 545 was due to switch contacts which are now fine because of increased frequency of use.

From what I've read here, the 5XXX (also cheap) series are mostly for medical and mechanical uses, nicely built and inexpensive but probably not suitable for RF or digital. I bought one (5103N-D11) for less than $20 and found a CRT for it for a bit more and donated it to a biophysicist where it was put to good use.

The TEK 2215, while a nice lightweight 50MHz scope, suffers from a very fragile CRT. Apparently there is a mesh near the face of the CRT onto which the beam is projected. The mesh is easily deformed by bumps - you see these scopes on EBAY in good condx in the $225 range. This is NOT a good scope for an undergraduate physics/EE lab! Unless you want to replace the CRT , avoid those with traces which are not absolutely perfect.

The biggest challenge these days is not parts availability, but ham radio's mental block on the subject. Parts are available. You just have to dig a bit sometimes.

You can get the Motorola chips in onesies and twosies from folks like Newark. They don't care if you're a ham or not. All they care is if you have the money. You will pay a premium for buying in less than OEM quantities, but that's how the game works nowadays.

A nice minimal parts count FM radio chip is the TDA7000 and offshoots like TDA7010T (the SMD version). Still current, still readily available. The last ones I bought came from Mainline (TDA7000) and Electromail (TDA7010T).

GEC Plessey packed it in years ago. I still have some SL6440 and SL6700 chips in my junkbox. No, they're not for sale. :-)

writes:

>If I have an air variable capacitor with no markings what ever anywhere
>on them, how can I measure the impedance to know if I can use the
>rascal?

Several ways:

First way is to measure the area of the plates and their spacing, then use the
following formula:

C (pf) = (0.224 x A) / D

where

A is the total area of all of the plates on either the rotor or stator in
square inches (use the smaller of the two)

D is the plate separation in inches

Second way is to use some sort of Q meter, capacitance meter or RLC bridge - if
you have one

Third way is to use a grid dipper and a known inductor. You put the known
inductor (don't use a toroid) and the unknown capacitor in parallel and measure
the resonant frequency by means of the dip meter. It's a good idea to check the
frequency with a frequency counter or general coverage receiver, because grid
dip meter calibration is usually awful. The capacitance can then be calculated
from the formula:

C = 25,330 / (F x F x L)

where

F is the frequency in MHz

L is theinductance in microhenries

C is the capacitance in pF

All three methods work, but the second way is the most accurate - IF you have
the test gear. The dipper method works really well too, but you have to do the
measurements carefully. 10% error is doing pretty good, btw.

How would CW stop this? All we'd get is:

.- -. -.-- -.-- --- ..- -. --. --. .. .-. .-.. ... etc

CW is not an acceptable behavior filter. In fact, if I had a dollar for
every time I had ... . - and ..-. ..- and so on sent to me (at high
speeds even!), I could buy my 20 wpm code test and have a "real" Extra
license before they go extinct. :-)

I am looking for a simple windows base program to do PC board layouts. I have been searching through the web and found a few that are free like Express PCB. Yes this one is free but the catch is that they will do your boards at about $120 US for 2.
I can print this one out but they mask it so you cannot build your on.

I am willing to pay for a program but not $400.00 + to do 1 single board.

Can you help me?

Thanks in advanced

In fact, this was abuse spam, not sent by the owner of the DSL hookup
named in the spam but by someone looking to harm him. PacBell abuse
personnel were intelligent enough to realize this, and are sending out
complaint replies informing people of this.

Yeah. Typically this newsgroup is about 20% articles that belong somewhere
else, most in rec.radio.swap. (I leave the spam marked "unread", then when
finished reading the non-spam stuff, compare unread to total articles in
the newsgroup. It ranges from 10% to 30%. Today it's lower than average,
15/125 or 12%.)

I've used one named EASYTRAX. It runs under DOS, although I think
it should run in the DOS box in Win95. I've been pleased with the
functionality and ease of use of it. However, it's rather ancient,
and you'll have to see if the output devices it supports are
available in your installation.

hi thanks for reading,

i have an ft890 that works fine on all bands and all modes except
cw, it will only put out milliwatts on cw ?in semi breakin and full.
i know it has not been modified for qrp as i bought it new.
i have tried all the usual things ,but still can get only milliwatts
out of it.
when you push the tune button on atio tuner in cw mode it will then
display full power for a split second as would be expected.

any help or info would be a blessing!

thanks in advance

Ed Lyons <elyons@sympatico.ca>
shared these priceless pearls of wisdom:

->I am looking for a simple windows base program to do PC board layouts.

www.microcode.com will get you to Circuitmaker and Traxmaker. They have a "student" version that will probably do your job. Our school has the full blown version, and I doubt I'd use it on an 8-layer motherboard, but for relatively simple (say, less than a thousand components) it does a very, very good job. It is quite easy to learn, and while there are inevitable "singularities" and glitches, it is no worse (and in fact really much better) for burps than anything else I've tried in the last 30 years.

For gauges around 26-30, its main use is for wire-wrap connections.
You'd have to go digging in old Bell Lab's stuff to see why The
Phone Company felt that the silver plating was necessary.

I've found that David Clarks seem to be susceptible to nearby RF
transmitters - even a handheld aviation transceiver putting out only
2 W if the antenna is nearby. A Telex headset I tried worked better,
so perhaps it's just lousy shielding on the DCs.

if you like, i can make a copy of the entire book... but i'll get a cost estimate to you for that.

as for being out of print due to parts no longer being available (as mentioned in another email posting), any ham with more than 4 working brain cells can get the circuits to work...

Does anyone know a source for 1/4" shaft couplers? I need one, possibly two for a project I'm doing.

Thanks in advance.

I have a new-old-stock roller inductor made by EF Johnson that I want to use in an antenna tuner project. It is ceramic with silver plated wire, and with a silver plated rolling contact. It squeaks and squeals terribly when rotated. Does anyone know if this thing can be lubricated, and with what lubricant?

Thanks in advance.

Ed OM,

Among all the other responses and sources you will get, look into
http:\\www.holophase.com.

Their CIRCAD program is very user friendly with a fast learning curve.
I have used it to design my SMT DDS VFO pc board, among other things.
Free download and use.

73 and GL,

Don, W6JL

721. BIG CW transmitter wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-26 00:00:00 UTC
From: Jim Berry K7SLI <basalop@gte.net>
Message-ID: <enwj4.2540$K26.47944@dfiatx1-snr1.gtei.net>

Hello Everyone,

I would like to find a WWII USN TCK transmitter. Have looked for years and have had no luck. This old rig used a pair of of 813's for finals and was rated nominally at 400 watts out.

Since I have been unable to locate a TCK, I am also looking for something similar. Say an ex commercial rig like a Mackay Marine that uses a pair of 813's.

Wish I had all the parts, I would build a transmitter using a pair of 813's. If you know of a homebrew one that needs a home let me know.

I would prefer a real grid driven transmitter. Not a GG rig. I do need a power supply (both plate and for the screens), control circuitry, a rack cabinet etc. Guess what I am saying is if you know where I can locate any part of transmitter, I might just be interested.

Ah heck, it does not even have to run a pair of 813's. Just be in the 500 watt output range, cover the ham bands, and I do not need any kind of modulation system since the rig will be used on CW.

I would sure like to find something in the PNW. The shipping cost of one of these big rigs can get a wee bit spendy, besides the hassle one has to go to just to pack the thing.

If you have any info, drop me a note at basalop@gte.net.

73 Jim K7SLI

I hope I am not the last to have one of these.
I am looking for a plate choke for a signal one cx7. I am using a junk part right now, so don't have 160m capability with the rig.
I will trade for a final tube, driver transistor, as well as the original engineers recommended mods notes that are not published. If you looked for these parts you know this is a great deal.

I would not worry about the hum you heard. You are picking up the residue of suppressed carrier. Try transmitting into a well shielded dummy load and then listen to your signal with another receiver without an antenna.

> What am I missing?

You're driving a pair of diodes, remember. You just want to get them
into a reasonably-saturated portion of their curves. The only thing
that matters is IMD -- if you can reach the manufacturer's IMD spec with
your particular LO, you don't need to lose sleep over exact impedances
and power levels.

If you ever see more than 1.4v p-p going into the mixer, it means you've
fried a diode or two.

Hello--

Actually, Barry is correct; I'm guilty of oversimplification in stating that
"Teflon" (Dupont's trademark) necessarily requires silver-plated wire for
oxidation
resistance during processing.

There are many variants of fluorocarbons, of which Gore's PTFE is one, Teflon FEP
is another and Tefzel (ETFE) is yet another. All feature different insulating and
chemical properties, and all probably require dfferent extrusion techniques.

Quoting from a 1985 copy of AT&T's Electronic Wire and Cable manual
(their publication no. 510-134): "...Tefzel requires the use of either a nickel- or
silver-plated conductor because bare copper wire cannot withstand the degree
of heat necessary to process and extrude Tefzel...."

Gore's processes may have rendered Tefzel obsolete, but there are plenty of fluorocarbon
insulations available to trap the careless<g>.

Hello--

Actually, Barry is correct; I'm guilty of oversimplification in stating that
"Teflon" (Dupont's trademark) necessarily requires silver-plated wire for
oxidation
resistance during processing.

There are many variants of fluorocarbons, of which Gore's PTFE is one, Teflon FEP
is another and Tefzel (ETFE) is yet another. All feature different insulating and
chemical properties, and all probably require dfferent extrusion techniques.

Quoting from a 1985 copy of AT&T's Electronic Wire and Cable manual
(their publication no. 510-134): "...Tefzel requires the use of either a nickel- or
silver-plated conductor because bare copper wire cannot withstand the degree
of heat necessary to process and extrude Tefzel...."

Gore's processes may have rendered Tefzel obsolete, but there are plenty of fluorocarbon
insulations available to trap the careless<g>.

73,
Brad AA1IP

Did you ever get your mod? I modified my 570D and it will not transmit beyond 29.995 MHz. I have held off buying the Ten-Tec transverter just because of this reason.

Have you considered asking Ten-Tec about changing the local oscillator from 116 MHz to 118 MHz? Then you could sweep your 570 from 26-30 MHz to cover the whole 2 meter band. The menu that displays the 144 sequence does not care where you start (i.e. 26 vice 28 MHz). Of course, you still need to mod your 570SG.

73 and good luck,

Scott Souva

Get a product called "Penetrox", it is a copper filled silicone grease, used in the electrical industry. I use it, and it works great. It can be used on antennas too. Another product for aluminum antenna connections, is called "Ox-Gard" by GB, found at "Home Depot".

I don't want to open a hot debate, but my question is this.
Has anyone sent detailed or documented occurrances of continuing
violations to a field office, and if so, did they care? Were you
contacted? Was the violation or occurances resolved? I am in
the process of gathering audio documentation of a violator, and
wonder if I am just wasting my time. All comments will be greatly
appeciated and thought about before continuing my effort.

I suggest silicone grease. It can be found in auto parts stores. A typical
use is hi-voltage spark plug wire boots.

738. Fun with NE602 6 meter converter

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-26 00:00:00 UTC
From: n2cqr@erols.com
Message-ID: <388eca0a.51565347@news.erols.com>
Source record: 63878

At a recent meeting of the Northern Virginia QRP club, I fell victim to K3CHP's stories about the joys of six meters. I returned home and started rummaging through my junk box and old issues of QST.

I came up with a Signetics NE602 chip (mixer, oscillator, and voltage regulator in one 8 pin IC) and a crystal marked 43.333 MHz. The January 1997 QST had a good article by WA3ENK "Junk-Box Converters for 6 and 2 meters."

I used WA3ENK's 50 MHz input tuned circuit -- in my case I used a piece of a Radio Shack nut starter as the coil form. Looks very cool. Where ENK used a TTL oscillator chip as the LO, I just used the junk box crystal with a couple of caps (as per the Signetics spec sheet). For the output circuit (around 7 Mhz) I used a parallel tuned circuit with a toroid, a trimmer cap and a fixed cap. I just guessed and put a five turn secondary over the toroid for the output.

Construction was a combination of dead bug and Manhattan techniques: I just glued the NE602 chip "feet up" onto the center of a PC board. I then started attaching components to the IC leads, using isolation pads where necessary. When the cuicuit was done, I used tin shears to trim away the excess PC board material -- this excess served as the "walls" for a PC board box that I built up around the circuit. With a couple of BNC connectors and a 9 volt battery, I was in business.

I had to use my Ramsey AR-1 aircraft band receiver to confirm that the LO was oscillating (I could hear one of the harmonics). Connecting the converter to my old Lafayette HA600 general coverage receiver, I tuned around and immediately located my own 49 Mhz baby monitor. If you build a converter for 6, and live in a populated area, you'll find lots of signals in the 49 Mhz range -- these will help you tune up your invention and will provide reassuring confirmation that the thing is working.

As luck would have it, the January VHF contest was just kicking off when I finished up the converter. So Six was filled with strong CW and SSB sigs. From my Northern Virginia QTH I heard stations as far south as Florida and as far North as New Jersey.

Unfortunately, I could also hear SSB signals that were obviously not from the 50 Mhz band (unless we were experiencing some very unusual propagation -- I was listening to ragchews from Germany!). They sounded like 15 meters. Trying to figure out what was going on, I realized that the 43.333 Mhz rock I was using was a thrid overtone crystal, with a funamental at 14.4444 -- just the thing to put a 15

meter SSB signal in my converter's output.

Signetics' spec sheet suggested a series LC circuit at the fundamental frequency from pin 7 to ground. I wound a toroid, found some suitable caps. Two or three soldering connections later the 14.444 Mhz oscillations (and the German signals) were gone. This was a very satisfying fix.

This little project was a lot of fun -- just the thing if you are looking for something that you can throw together in a weekend. I was thinking that you could probably use some 26-27 Mhz CB crystals (available at Radio Shack) with an output in the 24 Mhz range.

As I went through the project, I wanted to get a better understanding of the NE-602 chip. I wanted it to be more than a miniature black box. There is lots of info out there on this chip. JF1OZL's web site has an excellent section on the workings of the '602's Gilbert Cell Mixer. Check it out:
http://www.intio.or.jp/jf10zl/gil.htm
(Be sure to take a look at the rest of his amazing Web Site while you're there.)

Anyway, I had a lot of fun with this project and now can listen to the Magic Band. I'd appreciate hearing comments from others who've built similar devices.

John, get a can of spray-on electrical switch cleaner from an engineers supply store and give it one or two quick bursts. It nearly all evaporates within a few seconds and leaves behind a slight trace of lubricant.

The last thing you should do is daub silicone grease or odinary lubricating oil over electrical contacts - they will no longer be in contact. You might just as well use butter with bread crumbs in it.

Source record: 63882
Cross-posted to: alt.ham-radio.marketplace,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

I have this marine equipment available (I too would love to have a Mackay LF rig - they were gorgeous rigs):

Circa 1981 Scientific Radio SSB Marine Radio-Telephone, 1-KW Linear Amplifier, and Antenna Coupler for sale. All service manuals are available.

This is a continuous coverage (1.5-30 mHz) 10 channel crystal controlled system that was built for severe duty at sea. The tranceiver delivers 150 watts PEP (100w continous) to a 50 ohm load. It is capable of AME, CW, and FSK. Power finals are 3 6146A's.

The Linear is a servo-controlled unit running twin 3-500Z triodes and is capable of 1-KW keydown *output* into a 50 ohm load all day long.

The antenna coupler is also servo-tuned and will handle everything from a bent coat hanger to a long-wire at full power.

Tranceiver: SR-210MD - 8 x 16.5 x 17.5 inches, 50 lbs, 115/230 vac
Linear Amp: SR-110B - 20 x 22.5 x 50 inches, 260 lbs, 115/230 vac
Ant. Coupler: SR-650 - 24 x 20 x 10 inches, 73 lbs, 115/230 vac

This is a rather heavy-duty project package. Converting to amateur frequencies is a trivial thing. Cabling diagrams are included in the books. This system was working fine when it was decommisioned from a local tug boat fleet.

It's big, it's heavy - if you're not in the Pacific Northwest it is probably not worth the freight to get it to you.

Make an offer!

I use a product called "Tunerlub" made by GC Electronics cat# 26-01.
I purchased it at an electronic parts supply store. It is used to lube
TV tuners, switch contacts, relays and the like.

Note is used very sparingly and a small tube will be a life time
supply.

Since I do have a radio which goes there and listen on 10 meters half
the time, I have to say that I have heard maybe 3 or 4 CB'ers in that
low segment in the past 3 yrs. However, I have heard more bootleggers
on VHF/UHF than on the HF bands. There isnt anybody allowing CB'ers to
use The ham portions of HF legally. They usually dont last too long
when they are there and we must remember that other countries sell
radios as CB that cover these bands and may well be another country
you are hearing. While I do admit that there are CB'ers that go there,
I also find that in that segment there SWR is really high and that
deters them from coming back. Another reason I think that FCC doesnt
do too much about CB radio is the fact that DX kind of helps the cb
get away with alot since I know I dont want to travel 3,000 miles to
catch an operator in the act, plus the other countries that operate
legaly in those bands as CB operators kind of help to camouflage the
signals. That is funny about the roger beeps and weird talk.....

When I asked the question below, I just thought that there was some
news that I didnt hear.

A lower cost alternative to the ceramic chimney is to use an appropriate sized sheet of thin teflon held in place by a hose clamp around the anode structure.

Molybdenum disulfide works great. This is also used to coat soldering irons and aluminum antenna parts. It's sometimes called anti-seize.

Frankly, ordinary oil works most of the time if you only use a little. The squeak is probably comiing from the roller shaft. While it might seem that oil will insulate the contacts, it doesn't seem to cause a problem as long as you don't use much. And sometimes no lubricant at all, just a good cleaning will do the job. I have found an excellent and free lubricant is finger oil; I just run my warm hands over the surfaces and the squeaks go away.

Yikes what a racket those guys have. Check out
http://www.holophase.com and download the Circad program. There is a
DOS version and a Win95,8,NT rev. The "demo" lets you make a schematic
and small PCB. It's a "trick" to get you to try all the features and
say "Hey I like this" then when you want to build a more robust PCB /
Schematic you will want to buy it. While the list price is $995
licensed Ham Radio "Experimenters" or Students can get the same package
for $295.00 Give me a call (612) 492-3913 for details on the support
and updates. *It's a different scheme from the commercial version.
I'm a ham too and it's my crazy discount scheme that I talked the
Holophase Chiefs into.

752. Determining SBL-1 Mixer LO Power level

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-26 00:00:00 UTC
From: ae4jy@mindspring.com
Message-ID: <388f3e59.26022646@news.mindspring.com>
Source record: 63892

Am trying to get a MiniCircuits SBL-1 mixer working for a high level signal application and am having trouble getting +7dBm into the LO port. The RF and IF ports are terminated with 50 Ohms.
I thought the LO impedence was 50 ohms but appears to be closer to 15 Ohms at 4MHz and also is very non linear. I found an app note with a table showing a VSWR of around 3.5 at 1 MHz. The RF books I have assume the LO port is 50 Ohms and just say set the voltage to 1.4Vp-p.
My 50 Ohm signal generator tops out at +18dBm and it still will not drive the LO port to 1.4vp-p.
What am I missing?

Any thoughts on using the AD831 mixer and is it tempermental? Aside from it's price and noise figure, it's specs look a lot better than the diode mixers.

thanks,
Moe, ae4jy

info?

The prop pitch motors I've seen have been big PM DC motors -- two
connectors, and the polarity supplied determined the direction
the armature turned. My W.A.G. at E and I is 28 VDC, 30A nominal.

Good luck

I jsut finished my own homebrew receiver with this mixer. Don't get confused with this +7dbm. Yes you do need that amount of power, however put that power into a fixed 50 ohm resistor, make sure that the power level is +7 dbm, then connect it to the input port of the mixer. the 50 ohm resistor is only used to confirm that you have the correct power level. It is not connected to the mixer. The readings that you are getting when you connect the meter to the input port of the mixer are normal (screwed up). Basically confirm that you do have +7 dbm of power, connect it to the mixer, and then forget about it. By the way don't be afraid to call mini circuits, theyare quite helpful.

>Ohms at 4MHz and also is very non linear. I found an app note with a

This topic is very confusing and annoyed me so much that I eventually
decided to investigate it and get to the bottom of it. Basically,
the "official" answer is that you need to drive the LO port from a
50 ohm source with available power of +7 dBm. You are correct that
the impedance is much lower than 50 ohms and non-linear. So don't
try to look at the LO voltage to figure out if you have enough drive.
It will simply saturate at about .6V P-P due to diode turn-on voltage.
You can get an idea of how much drive you have by measuring the
current. It turns out that at the "official" drive level, the
current will be 30 mA P-P (counting just the fundamental frequency,
and ignoring harmonics).

If you want to "civilize" the LO port, put a series resonant LC
tank in series with it, with the reactance of the L and C around
150 ohms (not critical as long as it resonates at the LO frequency).
Then the source will see a linear non-time varying impedance of
25 ohms or so. If you want, you can then transform this to 50 ohms.
The series tank will make both the source and the mixer "happier"
although things will work OK without it obviously.

Also, you don't lose much conversion efficiency even at +4 dBM LO
drive and the mixer will be usable with higher loss to around +1 dBm
so in all likelihood, you are OK right now. You can also overdrive
the mixer by 10 dB with no harm.

When I was doing this sort of thing some time ago, I simply checked the
voltage across a 51 ohm resistor with a scope, and assumed that this
would be correct for the mixer input.

Bill,

Go to the QRP-ARCI homepage. Follow the links to QRP-L. Memebers
of theat list are always talking about homebrewing entire rigs from
scratch. This spring, they released a magazine that showed plans to
make en entire 40 mtr transceiver (superhet) using nothing but 2N2222s
as the active devices. No PCB either. just connections to pads glued
to a copper substrate.

There is a distinction between the LO port and the RF/IF ports. The RF/IF port terminations are an important issue and as you say the safest thing to do is resistively terminate then. You wouldn't want to put a tank circuit on one of them unless you were attempting some trick like reflecting back the image to improve the conversion loss (which can be made to work). OTOH, the source impedance used to drive the LO port is an entirely different discussion. In this case, if you have good LO isolation specs on the mixer, there will be no significant mixer products at the LO port so you don't need to worry about how they are terminated. In my experience, mixers work better if the LO source is a current source. IMHO, there is no justification for padding down the LO input with a 6 db attenuator unless there is a long cable between the source and the mixer and the source match is poor.

Helicals trade gain for bandwidth- so if you are looking for max gain/boom length, helicals are not your choice. In addition, you would need to have at least a pair, assuming you want to generate linear polarity.
Loop yagis (look at Directive Systems) do well. You would not need a very big dish to generate as much gain as a pair of long yagis- 1.5 meters or so, and the dish could be used on other freqs by changing feeds.

NEW OLD STOCK PERFECT CONDITION
0-100 MA RF PANEL METER METER USES A REMOTE SENDER TO
MEASURE RF. SENSOR CAN BE MOUNTED AT RF SOURCE (ELIMANATING SHIELDING
PROBLEMS). THIS WOULD MAKE AN IDEAL POWER METER FOR THAT QRP RIG.
Meter and Sensor Comes Packaged in Original Sealed Box
From Day of Manufacture, with Template and Mouniting Screws Meter
Face Size is 2 1/2" .Mounting Hole Size is 2'.
PRICE $10.00 Plus Postage $3.50 Priority Mail USPS.(United States
Postal Service}

Hi thanks for reading ,

i have a fault with my ft890 in cw mode it will only
produce milliwatts of power,the radio works well though
in every other mode .

anybody have the info on which pre-set controls the cw gain
or any other info on this problem would be a great help
i do have the schematics for the radio ,but not
the sevice manual .

thanks in advance

780. Re: Determining SBL-1 Mixer LO Power level

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-27 00:00:00 UTC
From: Yvon <rextel@naples.infi.net>
Message-ID: <3890E7C8.A99DD964@naples.infi.net>
Source record: 63785

Hello! Recently, I was experimenting with a 7 DBM mixer at 57 Mhz. I wanted to keep the LO level to the lowest value because the 57 Mhz signal and its harmonics were leaking into other parts of the design. I adjusted the source to 7 DBM into a 50 ohm resistor and also measured the voltage across the 50 ohm resistor; then I connected the source to the mixer, but the voltage was quite different. I wanted to experiment more but did not have time. The next thing that I want to experiment when time is available is to put a series resistor of let say 5 ohms in series with the input of the LO port and connect a
balanced transformer across the 5 ohm resistor and read the voltage on a spectrum analyzer.As the LO level increases, the voltage should start to increase more rapidly when the diodes in the mixer are conducting. It should also be possible to use a toroid core to make a current transformer with only a one turn primary connected in series with the mixer. Overdriving such a mixer at the LO port can raise problems if sensitive radio-frequency circuits are close to the driving circuits which can produce very high level of harmonics. Regards!

That's fundamentally a problem with shielding, though, not LO drive.
Backing off on your LO drive is not a smart way to deal with leakage.

Hi Guys,
I want to etch a large board and leave as much copper as possible as a ground plane. I usually use small boards and let the majority of the copper go, but I want to use a large ground plane on a couple of circs. How do you all cover this large surface to prevent etching?
I have seen commercial products, but know there must be a cheaper way, I have thought about taping or maybe rubber cement. Any ideas will be greatly appreciated. Thank you
ps, I am using ferric chloride etching technique, and generally use dry transfers and laquer pen.

Just how is the FCC giving it away? The last time I checked, The
license structure is still in tact, thus it isn't being given away.
If ham radio was going to turn into CB, It would have done it years
ago when the no-code tech license was invented. As for some on ham
radio that allready treat it like CB, They need to be dealt with so it
isnt inviting for those. Address the current problem, then deal with
what is up and coming.

>silver-plated wire for oxidation resistance during processing.
>
>There are many variants of fluorocarbons, of which Gore's PTFE is
>one, Teflon FEP is another and Tefzel (ETFE) is yet another. All
>feature different insulating and chemical properties, and all
>probably require dfferent extrusion techniques.

To be correct here, the word Teflon, when used alone to describe a polymer, _is_ PTFE, or polytetrafluoroethylene. Gore is the world's largest customer for DuPont's PTFE resins. Because Gore also buys PTFE from non-DuPont sources (ICI, Daikin, etc.), they use the generic polymer name. Gore also uses lesser amounts of FEP, PFA, etc.

FEP is a copolymer of tertafluoroethylene and hexafluoropropylene. It is melt processable while PTFE is not. The service temperature of FEP is lower than that of PTFE. Other fluorocarbon polymers include PFA (perfluoroalkoxy), ECTFE (ethylene chlorotrifluoroethylene copolymer, Kel-F, Halar), PVDF (polyvinylidene difluoride, Kynar), and ETFE (ethylene trifluoroethylene block copolymer, Tefzel).

Kynar and Tefzel have been used extensively in wire-wrap wire insulation. Some FEP and PFA are also used in specialty wire insulations (while they have a lower maximum use temperature and less chemical resistance than PTFE, some variations have a better crush resistance and optical clarity). Note, however, that these are not called simply Teflon.

>Quoting from a 1985 copy of AT&T's Electronic Wire and Cable
>manual (their publication no. 510-134):
>"...Tefzel requires the use of either a nickel-or silver-plated
>conductor because bare copper wire cannot withstand the degree
>of heat necessary to process and extrude Tefzel...."

>Gore's processes may have rendered Tefzel obsolete, but there are
>plenty of fluorocarbon insulations available to trap the
>careless<g>.

No Tefzel is not obsolete, it is just a different material than Teflon. And the Gore processes for producing PTFE insulated wire

are quite similar to those used by other companies too. PTFE is an unusual material that cannot be processed by conventional molding or extrusion methods. While some references may list a melting point for PTFE, it really has none. The temperature listed is that at which all crystallinity in the material disappears. Even above this temperature, the melt viscosity is too high for practical processing (and the polymer begins decomposition at these temperatures too).

Hello,

As my previous message says, I am looking for designs for those devices, I am really really looking for a transciever or a transmitter/reciever pair that would be able to have a output at 144MHz or 28MHz.... As this would really help for later transverter interfacing....

Would somebody be able to offer me a website that would have construction plans for a few basic digital packet radio devices?

Like a transciever(or transmitter/reciever pair), packet modem, TNC or something like that

I'm interested in getting into designing my own hardware but as any newbie have no place to start. Private Reply would be most appreciated...

Corky,

Get an old bottle of nail polish. Paint the unetched areas. I've
done this to an entire side of a double-sided board. Works perfectly,
but let it dry THOROUGHLY before you etch.

I'm tempted to add an antenna to my ATT 9520 (aka HS-8500). The
base unit actually has a short of coax from the PCB to the (apparently
resonant) built-in antenna. At a power level of approximately +24dBm,
I suspect I could even add a decent omni with a short run of coax and
remain inside scope of Part 15 (though I want to re-read it sometime
and verify this).

As it stands, that phone almost scares me how much power it runs. Certainly,
it has the best range of any cordless phone I've owned (and a fairly short
battery life!).

From: Yvon <rextel@naples.infi.net>
Subject: Determining SBL-1 Mixer LO Power level

Hello! Recently, I was experimenting with a 7 DBM mixer at 57 Mhz. I wanted
to keep the LO level to the lowest value because the 57 Mhz signal and its
harmonics were leaking into other parts of the design. I adjusted the source
to 7 DBM into a 50 ohm resistor and also measured the voltage across the 50
ohm resistor; then I connected the source to the mixer, but the voltage was
quite different. I wanted to experiment more but did not have time. The next
thing that I want to experiment when time is available is to put a series

resistor of let say 5 ohms in series with the input of the LO port and
connect a
balanced transformer across the 5 ohm resistor and read the voltage on a
spectrum analyzer.As the LO level increases, the voltage should start to
increase more rapidly when the diodes in the mixer are conducting. It should
also be possible to use a toroid core to make a current transformer with
only a one turn primary connected in series with the mixer. Overdriving such
a mixer at the LO port can raise problems if sensitive radio-frequency
circuits are close to the driving circuits which can produce very high level
of harmonics. Regards!

That's fundamentally a problem with shielding, though, not LO drive.
Backing off on your LO drive is not a smart way to deal with leakage.

Subject: Directional high-gain DX-antennas

Hey
Could use a few opinions on good directional narrowbeam antennas
for DX'ing only, mostly interested in L-band antennas, from 1200-1500.
Okey people say Helix's aint good, but for DX'ing I've read on several
places that it's good,
I guess most people will say yagis, well of course, but I'm looking into
every possible way.
Anyone have design plans on 23cm-yagis and phasing them?
Parabolic dish and feedhorn would be nice, but big dishes are hard to
comeby here in sweden.
Thanks

Helicals trade gain for bandwidth- so if you are looking for max gain/boom length, helicals are not your choice. In addition, you would need to have at least a pair, assuming you want to generate linear polarity.
Loop yagis (look at Directive Systems) do well. You would not need a very big dish to generate as much gain as a pair of long yagis- 1.5 meters or so, and the dish could be used on other freqs by changing feeds.

Hi Alan. I did this some years ago. I found that you have to power
the mic. Unfortunatly the lash up I created worked fine for some bands
but others had so much RF feedback I put my headset back in my flight
bag. I wish you luck. Please post if yours works without feedback!

The biggest challenge these days is not parts availability, but ham
radio's mental block on the subject. Parts are available. You just
have to dig a bit sometimes.

You can get the Motorola chips in onesies and twosies from folks
like Newark. They don't care if you're a ham or not. All they
care is if you have the money. You will pay a premium for buying
in less than OEM quantities, but that's how the game works nowadays.

A nice minimal parts count FM radio chip is the TDA7000 and offshoots
like TDA7010T (the SMD version). Still current, still readily available.
The last ones I bought came from Mainline (TDA7000) and Electromail
(TDA7010T).

GEC Plessey packed it in years ago. I still have some SL6440 and SL6700
chips in my junkbox. No, they're not for sale. :-)

>probably require dfferent extrusion techniques.

To be correct here, the word Teflon, when used alone to describe a polymer, _is_ PTFE, or polytetrafluoroethylene. Gore is the world's largest customer for DuPont's PTFE resins. Because Gore also buys PTFE from non-DuPont sources (ICI, Daikin, etc.), they use the generic polymer name. Gore also uses lesser amounts of FEP, PFA, etc.

FEP is a copolymer of tertafluoroethylene and hexafluoropropylene. It is melt processable while PTFE is not. The service temperature of FEP is lower than that of PTFE. Other fluorocarbon polymers include PFA (perfluoroalkoxy), ECTFE (ethylene chlorotrifluoroethylene copolymer, Kel-F, Halar), PVDF (polyvinylidene difluoride, Kynar), and ETFE (ethylene trifluoroethylene block copolymer, Tefzel).

Kynar and Tefzel have been used extensively in wire-wrap wire insulation. Some FEP and PFA are also used in specialty wire insulations (while they have a lower maximum use temperature and less chemical resistance than PTFE, some variations have a better crush resistance and optical clarity). Note, however, that these are not called simply Teflon.

>Quoting from a 1985 copy of AT&T's Electronic Wire and Cable
>manual (their publication no. 510-134):
>"...Tefzel requires the use of either a nickel-or silver-plated
>conductor because bare copper wire cannot withstand the degree
>of heat necessary to process and extrude Tefzel...."

>Gore's processes may have rendered Tefzel obsolete, but there are
>plenty of fluorocarbon insulations available to trap the
>careless<g>.

No Tefzel is not obsolete, it is just a different material than Teflon. And the Gore processes for producing PTFE insulated wire are quite similar to those used by other companies too. PTFE is an unusual material that cannot be processed by conventional molding or extrusion methods. While some references may list a melting point for PTFE, it really has none. The temperature listed is that at which all crystallinity in the material disappears. Even above this temperature, the melt viscosity is too high for practical processing (and the polymer begins decomposition at these temperatures too).

I've tended to use double-sided boards, and leave one side unetched. It
gives a good ground plane, but I don't have to worry about weaving big ground
areas around traces on the etched side of the board.

Anyway, I've never had problems using masking tape to mask off the unetched
side of the board.

Electrical tape worked too.

Tape is easy to remove. I've seen lots of schemes over the years, but things
like paint has the problem of removing it afterwards.

Des, I recommend the ARRL Radio Amateur's Handbook as an excellent reference on how these things work.

Further, there is a company (name escapes me at the moment) in the US that manufactures a single chip receiver that requires one crystal and little more to make it operate.

In these days of cellular telephone excitement there are many companies making circuits for transmission and reception at low power levels and with a minimum of ancillary components. Of course, using these components will not teach you all that much about how to design radio circuits, but it does offer a short path to a working model.

If you have any specific questions, let me know.

Many of us use commercial NNTP servers with built-in spam filters. The only time we ever even *see* spam on a newsgroup is when some #$@#$ on a non-filtered server propagates the spam by replying to it and quoting the whole damned thing.

Do you think spammers actually read newsgroups? Do you think publicly accusing them of being "spammers" will encourage even one spammer to turn aside from the path of spammerhood?

Same goes for the rocket scientists who keep perpetuating the "ANY YOUNG GIRLS..." thread. Knock it off!

I'm sorry, but what does this moronic spam have to do with cb and relaxing
requirements for licensing? I know that there are a lot of folks who don't
like the idea of the way restructuring has gone, but give me a break.
That's kind of stretching a bit.

Another possibility: clear box-sealing tape. It's strong, clear, cheap,
and 2 inches wide (so you need to apply fewer strips).

I've made small circuit boards by covering the whole board with this
tape, then using a sharp knife to cut two parallel tracks and remove
the tape wherever I wanted the copper etched.

The following is a list of tape and reel resistors I have for sale. The
first number is the value and the second is how full the reel is(est).

Asking $50 OBO plus shipping from 75061

There are 3 boxes, 32, 36, and appx 15 lbs.

That was in the back of my mind, but I've never tried it mainly because when I started making circuit boards years ago, I hadn't had contact with a wide variety of tapes. Probably any tape works, with the caveat that some probably stick better than others.

Certainly for RF with discrete components, it makes more sense to cover the board completely, and then remove tape where you need it, rather than lay out traces, and then fill in the ground area as much as possible.

I am reminded that in some cases, for maximum ground area but where "dead bug" style doesn't fit, one can use a Dremel tool with a burr or cutting wheel to separate out the islands. With that method, the only bare areas are where you've made the cuts.

I'll type slowly.

You asked, "Who is allowing CB'ers on HF?"

I answered, "The FCC."

Please note, the words "giving it away" were never used.

Your comment about no code techs are irrelevent to HF and CB, since they
were not given voice priveleges.

Some would argue amateur radio has already turned into CB, some before
the No Code Tech licenses were issued.

Dear Radio People,

My friend and I are thinking about doing a science project
that would require two computers to "talk" to eachother
using CB radios...

We don't want to transmit pictures or anything - - Just
simple text messeges. I need to know if there is a program
out there that turns letters typed on the computer to some
kind of signal that a computer can send and receive using
the CB radio as the carrier.

Please write back to:

G'Day,
I'm hoping someone can help me with a simple request which I'm asking on behalf of some microprocessor experimenters.

My main questions are geared towards building a low wattage (<500mW) transmitter which uses a removable crystal (27 or 40MHz) for frequency selection. The receiver would need matching capabilites (frequency modification via crystal subtitution) and AGC. I've a grasp on the concepts of FM Tx and Rx using PLL, but no practical experience. I have built my fair share of crystal sets, and so have an understanding of AM detection, but no experience using IF and subsequent mixers.

If someone has a URL for a "dummys guide to basic RF design" or something that would help (circuit diagram for RC Tx/Rx sets, or crystal based Tx/Rx pairs in the HF bands), I would appreciate it.
I'm using 27MHz and 40 MHz since they are the standard frequencies for RC cars in Australia. I plan on using crystals for RC cars (from high Q in Sydney) in my circuits. This way I'll be avoiding my experiments causing any issues with DOTC. The hoped for design will use a "data in" and "data out" pin in the transmitter, receiver respectively. I beleive that RC cars are limited to a bandwidth of 10kHz, so our processor designs would have to take this into account.

I would appreciate any assistance i can obtain. Most of us don't have a lot of the FR test instruments you would have, so designs which do not rely so heavily on these instruments would be appreciated, However if this reasoning is unreasonable, then please let me know. Please send info to des.bromilow@citec.com.au and to the list.

Many many thanks in advance,
Des Bromilow

812. Intelligibility - important factor for equipment (at least for mine)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-28 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <3890e953.2510657@news.online.no>
Source record: 63793
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.boathanchors

Improving intelligibility of receivers/reansmitters:

Remember in 1969 LA4O radio club were running a radio shack at an exhibition (LA1X) using a brand new Trio transceiver (not TS-500), and all public seemed to avoid us, but LA2DL installed his Drake TR-4, and suddenly it went rather crowded around the stand

Have been interested in how to implement good agc performance in my equipment, this happened after I got my first Drake 2-B receiver in 1969. I often wondered why Drake receivers have extraordinary good AGC performance while several manufacturers did not care for it until mid 80's.

The following cures have been found:
Trio TS-500, this is the worst agc I have experienced
Cure: Add a 22k resistor in series with large time constant capacitor (0.5uF?)

Yaesu FL-dx-500 (TX)
vast improvement on TX performance (intelligibility) was obtained with similar cure as above, believe it was 22k in series with 0.1uF capacitor in the ALC circuit Local English stations reported "now I can understand your English much better"

Heath-Kit SB-300/SB-301
Some AGC improvement is to use 1N4148 diodes as AGC detector, AGC voltage increased by a factor of two for an S-9 signal with SB-301. SB-300 was replaced by the 2-B, and I did not try AGC-improvement with it.
Also found another problem with SB-301 (SB-300), it is mentioned in Radcom TT(G3VA) in late 70's. RF amp (6BZ6) is unlinear, causes intermodulation. Grid 1 draws current, because it is too little bias voltage. Increase the screen voltage to 120V and cathode resistor for the same anode current as before.

Collins 51-S. (for SSB-only)
insert a 22k resistor in series with 0.47uF across the AGC-line. This is good for SSB and CW only, to include AM makes it more complex, but with the simple modification AM receiption with QSB it is worsened.

YAESU: FT-901/902 and FT-7 seem to work satisfactorily, while FT-726 and FT-736 seem to need some improvement. Worst problem with FT-726 seems to come from product detector, wrong supply resistor.

TRIO/KENWOOD TR-7010. Did some AGC improvement (in principal similar to Drake TR-4), but the main problem is that product detector diode

ring is biassed, remove this, and remove the two 30pF balancing capacitors to increase BFO drive level.

YAESU FT-101/101B, FT-221/FT225: AGC improvement failed and the reason seems to be rather strong carrier leakage which follows through the IF, seems almost impossible to cure. I did some extensive tests with FT-221. Carrier connection could be removed from the product detector and still SSB signal could be read as before. One suggestion for AGC is plessey SL-621/1621 audio derived AGC, but still IF signal is distorted, see HamRadio (abt R-4C)

R-4C: It is a problem with something which looks like carrier leakage, seems to be variable, may derive from xtal oscillator. Difficult when a separate product detector with 10kHz off-set BFO is used for cw meteorscatter receiption. This is mentioned in HR, but I don't agree, still it is very bad IF distortion without any connections to the product detector - whatever type is used, original or one using MC1496P.

The zero beat technique may not work too well with modern HF rigs. In CW mode, when the receiver display indicates 4.000 MHz, a 4.000 MHz incoming signal will produce a tone in the speaker at whatever setting you have chosen for the BFO pitch; *not* a zero beat. If the receiver doesn't have a BFO pitch control, the default is probably in the range of 700 to 800 Hz. If you tune the crystal to zero beat, its frequency will be in error by the value of the BFO pitch setting. Zero beating *will* yield the correct frequency if the receiver is set for SSB reception. However, in a receiver with good SSB filters, the signal may disappear before you get to zero beat, and you won't hear the pitch rise again as you tune to the other side of zero beat -- the signal is *gone*. So you can't really tell where to stop tuning. One way to check is to listen in both USB and LSB modes at 4.000 MHz; if you've tuned too far you will hear the signal on the other sideband.

The technique I prefer is to tune in a known signal (like WWV at 5.000 MHz) in CW mode, and set an audio signal generator to the same pitch as the tone coming out of the receiver. Then go back to 4.000 MHz without changing the BFO pitch setting, and adjust the crystal until the receiver puts out the same audio pitch. There are several sound-card based freeware audio spectrogram programs that will let you do essentially the same thing, without the need for the audio signal generator.

i'm sorry, i had just gotten done in the cellular newsgroup when
i responded to your post.

as for pots phones, i have a sprint 900mHz digital spread spectrum
a uniden model. outside antennae work well for me.
i have a few acres out here in the sticks and a big improvement was
gained.

817. HP 8553B Spectrum Analyzer Plug-In RF Section

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-29 00:00:00 UTC
From: Joe Schreiber <jschreiber@adelphia.net>
Message-ID: <G6Lk4.228$mG1.8134209@server2.news.adelphia.net>
Source record: 63648
Cross-posted to: misc.industry.electronics.marketplace,rec.radio.amateur.homebrew,sci.electronics.equipment

This is the RF plug-in for the 140-T and 141-T series spectrum analyzer mainframes. It tunes from 1 kHz to 110 mHz. It's in good cosmetic condition, the connectors look clean, and all knobs and switches are smooth... but I don't have the mainframe, so I can't test it. It was last calibrated 5-18-95. Please check my other auctions for the matching HP 8552B IF plug-in.

NO RESERVE!

If it were a good conductor don't you think it would short out your
connector?

I assume that you're packing the inside and mating faces of the
connectors. This is actually a good idea because it excludes air and
moisture and reduces corrosion. It doesn't prevent the metal parts
from making contact with each other where they are expected to do so,
but it is not a conductor.

Silicones are very good insulators.

For Sale: Japan Radio Corporation 60-5 picofarad vacuum variable.
Estimate 5-10 kv, Ceramic Construction with shaft head (1/4 inch shaft)
metal portions (excluding shaft) are heavy silver plated (tarnished). Unit
is about 10 percent larger than a Jennins UCS-500 and the same form factor.
Unit measures at specified values min and max. Full JRC nomenclature is:
VZ-60-20 HTS C 1054B

A nice unit for a 6 meter KW+ amplifier.

$100 post paid, insured, and double boxed conus.

Tnx for the read es 73

If you want to do pcb a few foot square, then just spray with normal pcb
lacquer or plasticoat. It can be removed with acetone if neccessary.

Maybe I'll type a little slower. The "giving it away" was stated,
Since the complete thread is not here, you cant see that.

About the No-Code Techs and CB, Your Right and Wrong. Again since the
complete thread was left out, The whole reply was towards HF/VHF/UHF
thus meaning "Ham Radio" like stated, Techs do have voice priviliges
on VHF/UHF the last time I checked.

I dont argue with the fact that others would say Ham Radio has
somewhat of a CB Attitude on certain frequencies, But I will say not
all Ham is that way.

There's something that's even better: you can get clear, self adhesive
plastic in sheets, I think about 1m x 50cm. Here in Brazil it's sold
under the name Con-Tact.

If you are in the US, try a local RadioShack store. I seem to recall
that they carry such a unit.

You might also try their Website at < www.radioshack.com >

Their catalog number is 273-242 and it should be available in most of
the stores.

While probably not legal on the CB guess that you could put them into a dummy load and be ok if you just want to transmitt across the room for a science project.

Look here for some sound blaster programs.

http://www.muenster.de/%7Ewelp/sb.htm

You might want to check out BTL .

While it says fo rmsdos, I have ran it under win98.

838. Trimming a crystal

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-29 00:00:00 UTC
From: Jack Edmunds <JEdmunds@prodigy.net>
Message-ID: <86v1ug$5rug$1@newssvr03-int.news.prodigy.com>
Source record: 63734

I am building a kit radio and has a 4.0MHz crystal that needs to be checked to see that it is running at 4 MHz. The suggestion is to set a hf rig at 4.00MHz and then adjust the trimmer until "the oscillator signal is at a perfect null or zero-beat".

I have adjusted the trimmer until the signal has become quiet. Is that what they mean by the above?

Thanks, Jack

You adjust so that the beat note gets lower and lower in pitch until it starts to go back up; then adjust to the lowest pitch you can get, which could be called 'quiet.'

There is an amp sold to the CB crowd call a 667. It will work on 6 with slightly reduced output as is. With some tweaking the full 600 wpep could be gotten but it doesn't seem worth the effort for about $250 new.

Silicone grease is an excellent *insulator*. When you use it on things
like RF connectors, the metal contact surfaces push the grease aside
and make metal-to-metal contact. The grease is useful because it fills
what would otherwise be air space, and keeps water out of the connector.

> I have an Eimac data sheet for the 3-500Z. Do the newer 3-500ZGs differ
> much compared to the original 3-500Zs, other than the graphite plates?

Steve,

I copied the information below from the RF Parts web site
(http://www.rfparts.com/).

COMPARISON OF 3-400Z and 3-500Z TUBES

EIMAC 3-400Z The Original grounded grid triode introduced in the early
1960s. Now obsolete part number. Power dissipation: 400w.

EIMAC 3-500Z Later version of 3-400Z having larger fins for the increaesd
power dissipation of 500w. Slightly larger body requires minor changes to
fit where 3-400s were used. Requires heat dissipating connector.

3-500ZG Graphite anode version of 3-500Z. Anode dissipation approximately
600w (additional air flow may be required). Graphite anode provides a more
rugged tube. Produced by Eimac, Amperex (3-500Z/8802), RF PARTS, Taylor,
Triton, etc.

3-500C Generic Chinese Graphite tube.

3-600Z Proposed Russia tube. Only prototypes were produced. Call for
information.

COMPARISON OF 3-500Z MANUFACTURERS

EIMAC Eimac was the original designer of 3-500Z line, and is generally
considered the "standard" for comparison. Eimac no longer produces 3-500Z or
other glass tubes.

AMPEREX An excellent graphite anode tube made of quality equal to Eimac
3-500ZG. Late production made in France and marked 3-500Z/8802. These
Amperex tubes require about 10-20% more RF drive than Eimac or RF Parts
tubes for the same power output. 90 day Limited Warranty from RF Parts.

RF PARTS "RFP" line is a quality graphite anode tube, and a copy of the
Eimac 3-500ZG. Probably represents the best value for the price. All tubes
receive 100% RF Parts' testing. 2 year Limited Warranty. Made in China.

TAYLOR RF Parts' 3-500ZG. A good tube at a very competitive price. 100% RF
Parts' testing. 1 year Limited Warranty. Made in China.

PENTA, JOLIDA, STAR, PRIDE, etc. Chinese import tube, quality and warranty
(if any) varies with brand and dealer.

>
(snip)
>
> Michael VE2BVW

Interesting comment on "size for the money". When I got the letter, I did some math:

According to the ARRL website, a 1 year sub to QEX for ARRL members is $22, and each issue is 64 pages long. At 6 issues/year, that's $22 for 384 pages of QEX or about 5.7 cents per page.

The last four issues of Comm Quarterly I received ran a total of 440 pages, and I renewed at a cost of $33. That's roughly 7.5 cents per page.

Assuming that a) QEX doesn't grow in size, and b) editorial content value is the same, then it would appear that current Comm Quarterly subscribers deserve a better deal than the (essentially) "one year of Comm Quarterly = one year of QEX" subscription conversion outlined in the letter.

Comments/criticism welcome, especially since I am still considering writing the ARRL circulation dept about this deal. Flames to /dev/null.

Hi Tony,
I got one of these about 2 years ago, and put it together. Worked
right off. Pretty good little radio. As a regen, it requires some
finese to operate, and the dial calibration leaves a bit to be desired,
but all in all a good rig.

Good luck

You might have better luck posting on the following newsgroup:

comp.arch.embedded

If you want to try rolling your own (if I can do it, anyone can!) You can get around MPASM by using a Parallax Basic Stamp II with it's very easy to understand and program PBasic language - plus there is a lot of info on driving LCD matrix displays. Take a look at www.parallaxinc.com or www.myke.com

The BasicX BX-24 is also pretty easy to program in a language which looks like VisualBasic -www.basicx.com - they also have a ng on onelist.com

Lastly, this month's PopTronics discusses "OOPIC" - which is object embedded programming - take a look at their website: www.oopic.com

If the violation occurred in a state that has their own radio misuse laws like West Virginia, it might be better to contact the sheriffs office rather than the FCC. What state is the violation occurring in?

"Wilkes" <rwilkes@gte.net>
shared these priceless pearls of wisdom:

->In need of circuit board layout software that can perform auto route.
->
->This is for personal amateur use. Nothing overly complicated!

I did a fairly exhaustive search of all the free/share/lowcostware programs for pcb layout and settled on Circuitmaker/Traxmaker from www.microcode.com. The "pro" version isn't terribly cheap, but there IS a downloadable student sharefreeware version that will probably do your job.

The nice part is that if you switch from personal/amateur use to professional use, there are steps along the way that will cost you a proportionate amount of $$ but your prior work will be supported by the updated versions. My hit is that the student freeware version IS the professional version with some internal crippling done.

The internal help files are very well done, and if you need a hard copy, the manuals are for sale.

front end : sanyo LA1186 used in almost all stereo BOOM BOXES for FM

PLL synthesizer : Nippon Precision circuits PLL2002: Use Motorola
MC145170 instead

Microcontroller : some stupid 4 bit NEC micro with 50 or so ports is used to
control the LCD and keyboard, use a ATMEL 89C52 with a telephone keypad
+ 8 *2 LCD .

IF amplifier : use motorola MC3361 , Ist IF = 10.7, 2nd IF 455 or 450

Most of these parts except the atmel and LCD can be found by taking apart an
old cordless phone !!! and a junk stereo !!!

If you are looking for low budget entry, I'd look into 2m handhelds on ebay. Then homebrew what you need initially. In other words, homebrew a beam and the 5w from the HT will be more than sufficient for local repeaters and those not so local.

For HF, I'd also look into ebay. But like always, buyer beware, although I've not had any problems buying equipment from fellow hams.

"ditdah" <ditdah@fastlane.net> writes:
>BULL SHIT

You're obviously better at shouting than measuring.

Take some silicone grease and put it on an insulating surface, like plastic or glass. Then take an ohmmeter and measure the resistance between two test probes that aren't touching. If silicone grease is a conductor, as you suggest, then the resistance will be measurable.

In fact, no matter how much grease you use, and no matter how close the probes are together (as long as they are visibly not touching), the resistance indicated will be off-scale (effectively infinite) for a normal ohmmeter. Looks like it's an insulator, not a conductor.

In fact, silicone grease is a better insulator than air, in the sense that a much thinner thickness will withstand high voltage without breaking down.

Dave

This is a controversial topic. My opinion (I'm sure some will disagree)
is that you want to feed a sine wave of current into the diodes and
let them make a square wave of voltage out of it. The reason for this is
that you have to pass the LO wave through a transformer and transformers
are much better for handling sine waves than square waves. It is quite
possible that phase shifts will cause the square wave to turn into a
not so square wave by the time it goes through the transformer. This
cannot happen with a sine wave. Secondly, for optimum IM3, the LO
signal should contain no even order harmonics. For a sine wave all
this requires is that you low pass filter it. For a square wave, you
have to generate exactly 50% duty cycle, and the output impedance of
the LO source must be the same for a logic high and a logic low or you
must pad it down.

Also, the distortion in a mixer is caused by the nonlinear nonzero
on resistance of the diodes, not what happens during the instant they
switch. Thus there is nothing magic about shortening this time with a
square wave.

The above notwithstanding, I have sometimes used differential ECL outputs
to directly drive mixer LO's in noncritical applications.

If you can be safely let loose with a soldering iron, the kits are
interesting and educational. You will get more bang from your buck
buying a used rig, but you will be a better ham if you build radios
instead of just being an "appliance operator."

>Tim KC8NQO

There are other kit manufacturers that DO have a respect for amateur
radio.
Ramsy produces kits that can easily interfere with amateur radio
operations such
as their wireless microphone kit that comes with a 2 meter crystal.
This is not only illegal for non-ham use but one way communication
is not legal with a license. They also sell a number of tunable
TV transmitters that are
able to tune the ham bands with little or no concern to make it clear that
their use
is illegal.
For kits I suggest you look at Ten Tec and Elinco. Elinco has a new 6
and 2 meter
receiver kit for around 40 dollars and they have training kits that are
easy to assemble
for the beginner that receive AM and FM broadcast band. I expect that for
now you are
interested in VHF stuff but if you want to build HF kits check out the QRP
sources.
Dan's Small Parts is a good source for parts and some kits. And their are
many others.

I have bought and built several Ramsey kits including the FX series and like them. A Ramsey radio, if assembled and tested by you, is easily modified for such things as computer control, scanning, other weird applications, etc, that one would hesitate to try with a "store-bought" radio.
Ramsey discontinued the 440 FX kit due to spurs and other problems that would not have been economical to redesign.
I'm a Ramsey fan and think their kits, especially at the new $99 prices for transceivers, are good buys, and their manuals and assembly procedures are worth the price alone. It is a very entertaining and educational process to assemble a Ramsey kit.
In the old days of kit building you had to be a decent "solderer" to get the kit working, but you really didn't learn any electronics from building it. With Ramsey kits, you build each section as a module, test it, learn how it works, etc, and really can absorb circuit theory and practice in the process.
That said, I have never built a Ramsey kit that didn't require mild modification or parts substitution (or replacing missing parts) to get working properly. Ramsey IS good about tech support and quick shipment of missing or bad parts.
I haven't built the Ten Tec kits but have read favorable reports on them, and the finished product is a much prettier radio, and likely works a bit better too, commensurate with the higher price.

Motracs have been used widely in repeater projects, but not in recent
years due to the tubes in the transmitter.
The receivers are good repeater receivers, with good selectivity etc,
and all solid state.
Sorry I don't have any specific schematics etc; just advice to get
manuals and use normal transistor/IC circuits for Carrier Operated
Switches to control transmitter PTT, etc.
They actually are not (IMHO) price-effective for repeater conversions as
is unless you want to "breed" them with some sort of solid state
transmitter, a much more complex project than just taking a Micor, for
instance, and adding a controller to make a repeater out of it.
BTW, I have a couple of MSY basket-case UHF repeaters I'll GIVE you if
you'll come to NM to haul them away. These are the successors to
Motracs, with Motrac-style receivers and all solid state transmitters
(called Motrans).

So don't let it get near to switch and relay contacts because it is
inclined to creep.

It's very good for keeping damp out of spark plug connectors.

One question, Rick:

Let's assume we are driving the mixer with the output from a sine wave
going through a limiter (perhaps this is from some sort of synchronous
detector scheme).

Even if the LO transformer saturates, aren't the diodes already biased on? How would the LO transformer saturation make any difference?

Source record: 63605

It depends. To do this properly, you need to make some decisions.

First, what is the source impedance and rise time of the pulses?
Second, what is the slowest rise time you can accept?
Third, what is the load impedance (complex impedance preferred)?
And finally, what is the capacitance of the shielded cable?

You have a voltage divider here that is frequency dependent. The capacitance of the cable is put in parallel with the load. So you have a low pass filter, and the cutoff frequency will determine the degradation of the pulse rise and fall times.

All this presumes that the cable length is a very small fraction of a wave length at the highest frequency component of concern. If this is not the case, then tell us the cable length and velocity constant.

So it's not that simple. Give us some of the parameters above and we can help figure out the pulse degradation.

Message-ID: <X0ll4.560$OI1.23105@news5.giganews.com>
Source record: 63606

The things that can go wrong with the tubes, and for which you ought to test, are:

1. interelectrode shorts
2. Insufficient filament emission
3. gas

The proper procedure would be to apply filament voltage, then measure plate to grid, plate to filament, and grid to filament resistance. (Make the plate and grid negative with respect to the filament.) If the resistance is high, while gently tapping the glass (lightly snap your fingernail against the side of the tube), there are no shorts.

Apply grid bias and plate voltage. Measure plate current, according to the tube characteristics in the book, being careful not to exceed plate dissipation ratings. If the current is within about 10% of the data, and there is no blue glow in the tube, you are probably okay. The current should also remain steady and not fall off. It's not important to apply a high potential to the plate but you should try to operate at a fairly high plate current to verify the emission capability of the filament.

Source record: 63607
Cross-posted to: rec.radio.amateur.homebrew,uk.radio.amateur

I found a better way to print meter scales.

I carefully remove the scale plate from the meter and put it in a scanner. Take the scanned image and alter it as desired with any graphics program, then print.

Cut the printed copy to size and paste it over the scale plate. If you don't want to mess up the original, turn it over and paste it on the back side. Then reassemble the meter (back side out if you did it that way).

I did this with some meters that had black face and I wanted white face. I didn't alter the markings but inverted the colors and got a lovely result. It's worked great with no problems.

But you must be very careful not to damage the pointer or bearings nor allow any metal pieces to be attracted by the magnets.

Date: 2000-01-31 00:00:00 UTC
From: Joe Malloy <jmalloy@borg.com>
Message-ID: <3895dcdf.0@nntp2.borg.com>
Source record: 63608

I'd buy a T-Kit (by Ten-Tec) rather than a Ramsey. I built an audiofilter sold by Ramsey electronics, model AF-1, and it works quite well, has a nice feature of its own rectifier so it doesn't matter if you hook up ac or dc (and the dc can be connected either way!). But the case and controls are rather flimsy, sorta like the the input and output jacks are, in that they're mounted on PC board and rely on solder connections (largely) to keep them put. This kit isn't constructed in a way to inspire confidence. On the other hand, I also assembled a 1330 -- the 30M version of the Ten-Tec kit series -- and I think it's like a tank! You have to be careful with the board and the two mounting plates (one is the heat sink for the output and one hold the three pots) but once assembled into that steel trap they call a case, nothing short of nuclear bombs would hurt it! (Ok, so I exaggerate a little bit!) It works very well, too.

You might want to consider the Small Wonder Labs stuff by NN1G -- I just built the DSW-40, a 40 QRP radio that's digitally tuned (and hence rock stable), with its own keyer, frequency annunciator (press a button and the things reads you back your frequency in morse), RIT -- you name it, it's got it -- all except an AGC, but that's expecting too much, me thinks. And it's small! It cost about $130 complete, so it's somewhat more expensive than Ten-Tec, but it's a blast (hmm, that missing AGC....). It's available for 80, 40, 30, and 20 (so far). Check it out. The only problem I'm having is transmitting: I can hear the LO putting out a signal, but I don't have any voltages in the amp circuit...but give me time!

I'd buy a Ten Tec before I'd buy a Ramsey kit. I've built a few of
Ramsey's kits. The problems I've seen mostly relate to unreliability.
Often they lack enough decoupling capacitors of a reasonable type.
Once you add those capacitors in to the picture, the projects tend to
work much better.

That said, if you don't mind the fuss factor, Ramsey's kits usually
work.

Incidentally you may want to check out the web site for Ramsey's
account of a federal raid on his operation. Even if only a few parts
of his account are true (and I have no reason to doubt any of it) this
is a frightening use of the office of the Federal District Attorney.

Source record: 63613

Sandor,

At the risk of disagreeing with the other replies, you should have no real problems with using a diode between each power supply and the rig.

A cheap way to try this out is to buy a 25 A bridge rectifier ($4) and connect the + terminal to the + terminal on the rig and the other terminals marked with a ~ AC symbol to each power supply +ve terminal. The -ve terminal of the bridge is left unconnected. You will need a heat sink on the bridge rectifier and preferrably a little thermal transfer compound between the two.

Connect the -ve outputs from both power supplies together at the - terminal of the rig.

This setup will drop the voltage output from the power supply (13.5) to around 12.5 or less at full load.

You can try this out with one power supply at a time, if you want.

When I was talking about the transformer not passing a square wave,
I was referring to phase shift problems (or you could describe it
as different group delay for different harmonics). This is a problem
even at low levels where the transformer is linear.

I can't imagine why you would want to saturate the transformer in
a mixer.

Yes, I have read the Steinbrecher patent. He has a clever topology
that causes the transformer to see a constant linear resistive load
rather than the usual "funny" load of the diodes. In this case,
you actually have some hope of getting a square wave through the
transformer in decent shape, although you have to extend the
frequency response of the transformer considerably. This is a
great mixer but comparing it to an SBL-1 is apples vs oranges.

The suggestion should have been complete enough to state that you need a hf rig with a bfo to check the crystal. That is a rig that can receive SSB or CW. If all you have is an AM rig then use that quite spot as you are in the neighborhood and good enough. The others that have recommended procedures are fine if your rig has a bfo and that is a bit more accurate way to do this.

I have an old Kenwood TR-7850, and while I really like the radio, I do have one complaint. The scan rate is *glacial*. On the order of 1 or 2 channels per second. While I don't consider this a huge problem, I'm wondering if there's a mod to speed this up. Or is the problem just that that's all the faster the PLL can lock onto a new frequency?

911. Re: Determining SBL-1 Mixer LO Power level

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-31 00:00:00 UTC
From: Graeme Zimmer <gzimmer@bigpond.com>
Message-ID: <rJ5l4.2786$VJ1.5183@newsfeeds.bigpond.com>
Source record: 63690

I been wondering about this for ages.....

If the diodes in a ring mixer are truly switching (and not just running in their square-law region)..... why don't we always drive a DBM with a square wave ?

Or to put it another way, why is a sine wave important (eg why low harmonic content) if we must ensure sufficient LO level to make sure that the diodes are acting as switches ?

Am following the thread with great interest

direct replies would be appreciated.

regards ..... Zim VK3GJZ

Shouldn't be a problem, assuming it's shielded or at least UTP
(unshielded twisted-pair), and not used in an extremely noisy
environment.

915. L.O.S.A - List of Stamp Applications [000127]

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-01-31 00:00:00 UTC
From: cjX@hth.com
Message-ID: <3892f934.3882074@news.sverige.net>
Source record: 63694
Cross-posted to: comp.robotics.misc,comp.home.automation,sci.electronics.misc,rec.radio.amateur.homebrew

Hi,

Below is the latest index of L.O.S.A and you can download the
complete L.O.S.A from the following places...

WWW:

http://www.hth.com/losa/

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially Guy
Gustavson's story (see #001) about how he saved his beloved cat Kesha
gave me the inspiration to start writing L.O.S.A. I hope Kesha still
is alive and having a great life. Now 4 years later there are 150+
applications described and I hope you will enjoy reading all (or
parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa/

1.2 Why are some links dud's ?

Since people changes their e-mail and web addresses some links may be
dud's. If you previously contributed with one (or more) of the
applications please take a quick look and check your e-mail address

and/or web-links. I'm only able to keep the list updated if I'm
informed about changes, thanks in advance.

1.3 List of contributions

Howdy:

Need help matching D-104 mic to FT-920 (Yaesu). Aside from the connector selection, can any "GURU-ELMER - HAM" tricks of the hobby be shared. Perhaps, other research can be suggested. A "point" in the right direction would be a great start.

Thanks in advance.

>I can envision a situation where the hysteresis effects of a
>transformer might cause a phase shift of the LO once it gets to the

The distortion of a square wave by a transformer can occur without
any nonlinear core effects such as hysteresis or distortion. If
you pass a square wave through any network, such as a transformer,
than does not have flat frequency response and linear phase, you
will get a distorted square wave out. It may have overshoot, it
may have rounded off corners, and/or it may have droop. Thus the
waveform that is presented to the diodes will not be a perfect
square wave and it will not turn the diodes on the same as it would
if it were a perfect square wave. Suppose the transformer winding
capacitance causes a funny suckout at some harmonic of the square
wave. If you delete that harmonic, the wave will acquire a bunch
of wiggles. If you had used a sine wave, you wouldn't have to
worry about a suckout at a harmonic.

I hope that answers the question, and again, I never said you can't
use a square wave, it just isn't generally the optimum thing to do.

The reasons for not using a square wave have nothing to do with
core saturation.

>Seems like it would be an easy enough test to do. You'd want to know

I don't remember seeing anything about that in his book. It is
excellent for what it covers, but it doesn't cover everything.

I did some characterization of a W-J M9E mixer in conjunction with my
1996 FCS paper, and I found that it was critical to heavily low pass
filter the LO drive to the mixer in order to get the best IMD.
So that is some kind of a data point.

If you propose to use a square wave, tell me how we generate this
square wave. How do we get exactly 50% duty cycle? I can get
arbitrarily close to 50% duty cycle if I use a sine wave by just
filtering the dickens out of it.

Well, W-J doesn't recommend this. I would tend to believe them.
Mini-Circuits' talent lies in low cost manufacturing, not mixer
theory.

Try the specialist repair parts distributors like MCM and Dalbani
(or the NTE and ECG universal replacment stuff) for consumer stuff.
I can't think of any other easy way to get east asian chips. And
it seems that Toshiba, Sanyo and others have that market these days.
And for newer chips you can even find the datasheets if you web surf
their .jp (in Japan) web sites. (The .com ones are often their US sales
operations and are worthless for anything not new or digital).

Hmm,
I guess there more to this than one might thing at first sighting!
The "Paramixer" made by Steinbrecher in the late 80s did use matched
diodes for switching but used fet-drivers to get the square wave!

This mixer acheived IP in the +50 dBm performing excellent!!

Wish I had more information about this one.

Anyone read the patent??

In many cases the antenna is NOT resonant on the frequencies used.
So the LCs are to match the transmitter to the existing (Sub-optimal)
antenna.

The circuit provides for a reasonable match to the tranmitter so it may
produce full power.

The rules for impedance matching are in the ARRL Radio Amateur's handbook.

there are a number of step you must take when designing a matching network.

Good trick Bob, make sure that the printer is printing true 1:1 scale
Should you get filings in the magnet plasticene or putty is a good way to get them out.

Gary7SLL, wondering how to generate a semi circular log scale with a graphics package.

Howdy, folks.

New site! http://cw.hfradio.org - CW / Morse Code Resrouce center. Lots of stuff coming down the line. If you have stories, tips, links, and other things, would you share them with me, and allow me to post them on this new resource?

Also, if you are into HF, consider getting onto 10 meters! It is hot right now. Lots of DX. The Ten Ten International club is challenging Amateurs to work 2000 contacts on 10 meters, any mode, any 10 meter frequency, in the year 2000. I've posted my current 10 meter logs on the site. See if you are in there (if ya worked me!).

As usual, you are also invited to visit http://hfradio.org - a non-commercial site offering:

+ Azimuth Map / Equidistant Map Creation (choose any QTH as center, many options)

+ Propagational Resources (live, real-time reports, eAlert service (sign up for automatic email solar/geo reports, complete with Aurora index))

+ News, and DX information and reports

+ QSL Manager and Callsign Lookup center

+ Swap and Shop

+ FREE HOME PAGES THAT YOU CAN USE TO POST YOUR OWN HAM OR SWL SITE

+ Bookstore - SWL and Ham related books. Over a 1000 titles so far.

+ Plus more (Directories, etc.)

I wouldn't *want* to saturate the transformer, Rick. I'm merely pointing out that once it does saturate, wouldn't the diodes already be switched in to conduction?

Let me restate the question: Would the group delay effects of a square wave signal propagating through a transformer actually cause a diode to drop out of conduction when it is actually expected to stay on? Conversely, would group delay effects through the transformer actually cause the diodes to stay in conduction when they're supposed to be switched off?

I can envision a situation where the hysteresis effects of a transformer might cause a phase shift of the LO once it gets to the mixer diodes. And I can envision that using a square wave on the LO port might result in a different phase shift. But I can't see how it would necessarily be a "bad" thing if you consistently drove the input with a square wave.

AutoSketch will do it. If you calculate the angles involved - measured
from a baseline, and centred on the pivot point - you can make
AutoSketch draw a scale mark at any specified angle using keyboard
input. It's tedious but very precise.

Linear scales are very much easier - it will draw all the lines in a
single operation (once you remember how).

Richard OM,
I made my own pattern manually. You can do this just by sitting down and making a sketch of the pin placement dimensions, and then use your favorite layout program to make a part macro. I am aware of no ready-made PC pattern available on any of the free/share ware PC layout programs that I use. But they must in general exist somewhere, since it is a standard 80-pin SMT package pinout. In the time it may take you to find a source, you could lay out your own pattern and save it.
The AD9854 is a great looking part. Programmable CW keying rise and fall times, even. Ham radio homebrewing is getting easier and easier every day. Ain't it great?

I'm aware that there are those who would suggest you drive the LO port with a square wave current source. It seems to me that there is no danger of saturating any cores that way, any more than if you drive it with the same current level some other way.

Seems like it would be an easy enough test to do. You'd want to know what things you wanted to characterize: IP3, P1db, etc. Surely someone out there has done tests like this before. Is there anything definitive in Steven Maas's book on DBDM's? (I think that's the guy who has written books and magazine articles on the subject.)

I'd love to be able to ask my uncle his thoughts on it; he got a patent for at least one version of a diode DBM. Unfortunately, he's beyond being able to discuss things like this.

Cheers,
Tom

For what it's worth, the FAQ in the Mini-Circuits designer's guide
claims it's perfectly kosher to drive their DBMs with a square wave.
Don't have the exact quote handy, but it's one of their FAQs.

I'd like to instal Auto CAD 13, but at that price no way.
I think it has a function for doing log type work directly.

Presently I only have graphics packages.

If a CAD package can Auto draw linear scales then it is not very hard to get it to do Log or any other law. I have written BBC Basic programs to do it on a nine pin Dot matrix, but the output is really no up to scratch.
Ideally a C program for Windows that would pring scales of various sorts woul dbe a nice application for Hams.
I suppose I could calculate a function with Excel and then print a scaled graph of the function and cut that out.

> Linear scales are very much easier - it will draw all the lines in a

Be nice if it put on the numbers too :)

Thanks Ian, little tools like this can give a professional touch to home construction projects. A laser printer will print on transparencies, an entire front panel could be printed in mirror and the stuck onto the project before the components are mounted on the panel once stuck firmly down then trim with a sharp knife. Because the print is under the plastic it is protected from wear and sweat bringing it off. Also any Logos etc can be put on nicely.
Got any easy Ideas for mechanical methods to convert linear motion into Log, Tan, etc. motion?

947. Re: Wire antennas and tuned circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-01 00:00:00 UTC
From: dm <dmandjos@olypen.com>
Message-ID: <KuKl4.3573$d61.106096@news6.giganews.com>
Source record: 63644

I built three(3) R/C xmtrs, and four (4) receivers, which I used happily fly , until I got TOTALLY sick of the jerks that fly R/C toys!!!

BUT, usually the antenna you trail from your plane, or if you are "cool", you bury inside, is usually only about 30 to 35 INCHES long. That is a long way from resonant in either the 6 Meter ham band, or the 74/76 MC "R/C" band, Sooo, you need to be able to match that wire to the input of the rcvr. That means you are trying to make a 30 to 35 inch wire, look like from 58 inches on the 6m band to 37 inches at the channel 60, I believe. Anyway the top Red Steamer channel! AND that is the purpose of that tuned circuit. for the R/C channels, the matching effect is not much, thus the "Q" of the circuit is pretty low, the tuning of that circuit is not too critical. For the 6M band, it is pretty high "Q", and when I tuned my receivers' inputs, it was a slow, cautious affair! But it worked just great. I found it very handy to have a spare receiver, for use while building, setting servos, etc. I also used that rcvr with a stervo, to test my operating range, here at home, with the xmtr antenna fully compressed, and pointed at the rcvr/servo. This way, I knew that a TX/RX pair better run that servo (Flag on the servo shaft) from about 400 feet! Only crash I ever had was from a cold solder joint in the TX..it just didn't put out the 0.6 to 1.0 watts, and so the range was too small, and my twin engined jewel went.....ker-plop! R/C a fine hobby, IF AND ONLY IF, you can fly away from a CLUB. R/C Club gotta be the biggest collection of the smallest minds this here HAM ever saw!!! GL with PCM!! 73 "DM"

951. List of the rec.radio newsgroups

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-02 00:00:00 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <8782od$8fr$1@news.hawaii.edu>
Source record: 63556
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

```
Archive-name: radio/personal-brief-introduction

In an effort help ensure a poster's article reaches the appropriate
audience, below is a list of the rec.radio newsgroups. In most cases,
a group's name will explain its purpose. Cross-posting should rarely
be necessary.

rec.radio.broadcasting (devoted to the broadcast industry; moderated)
rec.radio.cb
rec.radio.info (periodic informational bulletins; moderated)
rec.radio.scanner
rec.radio.shortwave
rec.radio.swap (for buying, selling, and trading; not a discussion group)

rec.radio.amateur.antenna
rec.radio.amateur.boatanchors (tube-type communications equipment)
rec.radio.amateur.digital.misc (packet, pactor and other digital modes)
rec.radio.amateur.dx (long-distance amateur communications)
rec.radio.amateur.equipment (questions, comments regarding commercially-
built amateur gear; not for buying/selling)
rec.radio.amateur.homebrew (devoted to home-building ham gear)
rec.radio.amateur.policy (issues include code, restructuring, local
restrictions in conflict with FCC R&R)
rec.radio.amateur.space (satellites, meteor scatter, EME)
rec.radio.amateur.misc (any topic not covered in the above groups)

(At least two other English language radio hierarchies exist, prefixed
with "uk" (United Kingdom), and "aus" (Australia), in place of "rec.")

Again, cross-posting should rarely be necessary. Many times, a long-
running thread results from a single cross-posted article, and its
content drifts further and further away from being "on-topic" in the
various NGs which receive each and every followup.

For more detailed information, see "Guide to the Rec.radio Newsgroups"
posted on the 15th of each month.

Jeffrey Herman, KH6O

Source record: 63557

In my real job I can call up a consultant and say "Run some 100BaseT from that wall to that wall", but this is what I supposedly do for fun.

The terminal impedance can be figured as a CMOS counter input. The pulse width is specified between 125 and 500 nanoseconds, but it has really rounded off edges (even with a good TEK scope probe). I have no info as to the source impedance (not given in the mfr's data sheet). The cable I have at hand is Belden 8641 (shielded with a separate ground return and a line for powering the counter). Being a miser I am happier to use something at hand but I am open to expert advise since Allied Avnet is only a few clicks away.

While I have been running the pulse through a pair of flip flops to clean it up and stretch it out. The existing (pre-ff) output is not really pretty, but perhaps it is better to do without the clean up (or conditioning) ff's, since the nice square edges off the ff's are probably prone to problems.

I am all ears.

953. Quadrature detector

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-02 00:00:00 UTC
From: JW <jdwalton@home.com>
Message-ID: <3897CE34.7B30365C@home.com>
Source record: 63558

One last digital question.

I mocked up a quadrature detector to read the first 90 degrees of a sine wave. Easy, I thought, multiply the input frequency by 16 (using a 4046 as a frequency multiplier) and, with a CMOS BCD counter, just "NOT BUFFER" (tying together the inputs of 2 NAND's) the 2^2 and 2^3 outputs which are "0" for the first four counts), NAND these two outputs and look at the result.

Everything is clean, except a pesky little spike -- faulty wiring off the bread board? Opinions please. The original idea is from an old issue of EDN for a 0 to 90 deg quad detector.

Jack

954. Re: Want to build VHF/UHF duplexer

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-02 00:00:00 UTC
From: neep.neep@acme.com
Message-ID: <n08f9sst9mslomfkd64qs9934lq6cq68dr@4ax.com>
Source record: 63559

QST had an article several years ago. It was a capacitor input high
pass filter and a inductor input low pass filter with input terminals
connected.

Cutoff frequencies were well above/below the target frequencies.

You are quite right the more complaints the better. It is easy to ignore one or two complaints, but when a couple dozen complain ("CC-"ing your Congressman helps to get the ball rolling!), things sometimes get done. Still, the process takes a long time. In the Phoenix area, there are two or three high-profile (meaning that they get reported in the ham press, and even sometimes in the local newspapers) enforcement actions each year against CB operators. Last year they got one who was retransmitting Channel 19 on a 2M repeater, and vice-versa. He was so hostile and abusive to the FCC agents they hit him with a $6K NAL. Then he kept it up, and apparently a neighbor, sick of rampant TVI, threw a molotov cocktail at his tower. In the ensuing fire and commotion, he (the CBer) got arrested for disorderly conduct, another complainant-neighbor who is a ham notified a contact at the FCC office, and he ended up having his CB, illegal amp, dual-band FM mobile and brick-amp, and an illegally modified AOR 8000 confiscated. Very satidfying, even if it took over a year. In another similar case, the County Sheriff's office is after someone who is coming on Sheriff's frequencies and threatening the Sheriff (who is a horse's ass, but that is beside the point here). This has been going on over two years with this individual, and there have been several other instances just like it in the city of Mesa, Arizona where teenagers were caught using and jamming police repeaters. The moral is that it takes a long time to get conclusive action, given both the budgetary and logistical problems of catching these guys.

BTW, while making death threats using radio involves the FBI, your chances of getting the FBI actually interested in a specific case are slim and slimmer. I don't say none, since anything can happen, but just filing a complaint with them isn't likely to bring any sort of action at all. They are very busy. They probably will tell you to call your local police, and get a restraining order of some kind oif the threats are directed at you. Only if you can provide tapes, DF data, TC fingerprints, and dates/times/names/places, and evidence that the person transmitting is likely to immediately act on the threats will you get any kind of action, from the police or FBI. Even then, the police can't make an arrest based solely on a verbal threat. There has to be documentary evidence of past violence, or else the current threats must be accompanied by actual menacing: i.e., the offender must be holding a pipe or a knife or a gun in his hand as he says something like "I am going to beat you/kill you pretty soon." Pretty hard to show that over the radio.

Adam & Tim,

It is illegal to use CB radios to transmit computer data, or anything other than AM-modulated voice signals. If you keep the transmitted output power down to 100 milliwatts or less, which is plenty of RF power to accomplish the short range task you have in mind, you may be able to use a pair of 49MHz walkie talkies, or FRS walkie talkies, or else you can get a pair of small FM wireless microphones along with a pair of FM receivers tuned to an empty spot on the dial (you can get all of these at Radio Shack and other places).

You also need at very least a sound card and data controller/modulation program for each computer. You can find shareware and freeware programs at www.qrz.com or www.ac6v.com. Another thing to try is using a pair of used terminal node controllers (TNCs) with the radios and computers. You can find these used at hamfests and on the internet.

Whatever apporach you take, this is a fairly complex project for a beginner. I don't mean to discourage you, just letting you know. you might look up your local ham radio club to find someone locally who can help you with the project, since there is a lot of wiring, configuring, tweaking, debugging, and even possibly some soldering involved. Maybe your science teacher can help you find ham operators in your area, you should ask him or her. At very least, go to your public library at look up books on ham radio and data transmission. The ARRL Handbook for Radio Amateurs and Your Packet Companion are two good titles to start with, though look for anoything that deals with radio-data communications. Best of luck to you!

Tim,

The Ramsey kits are interesting, but for the money you would be much better of getting a new or used 2M mobile rig. Kenwood, Yaesu, and Icom each sell a model that retails for about $200 new. Alinco and ADI have 2M rigs for about $175 new. For your money you will get a full 50 watts out, a digital display, memories, PL/CTCSS encode-decode, and a DTMF mic. You also get an assembled radio with a full warantee that is ready to use, just connect a 12V supply and antenna and away you go. Kit building is fun, but I think, as a new ham, you will have more fun, and be better off, buying an assembled rig. You get more for your money, and avoid construction problems. If you have the itch to build something, by one of Ramsey or Ten-Tec's accesory kits, like a wattmeter, or even the 2M-to-6M transverter. That way, if you get into trouble building the kit, you can hop on a repeater and get help from another ham, which you couldn't do while building one of the Ramsey radios (at least if you don't have another rig). Best of luck to you!

In the 2-way radio business, as well as broadcast radio, telephone lines have been used for both audio and control tones and switching voltages to control radios from a distant point.
Telephone audio is not hi-fi, but neither is the audio we use for radio SSB/FM bandwidths either.
You can still buy inexpensive remote control units that use DC voltage to operate the PTT relay as well as decent audio for both transmit and receive,with only the 2 wires of the phone line, and it is not terribly hard to build one yourself.
Biggest trouble is that nowadays a "dedicated line" of ANY length provided by the telco will cost a fortune. Thus the use now of remote controllers using tones for TX/RX control so that the desired remote radio can be just "dialed up" like a telephone.
There have been articles in 73 and QST detailing such projects. You can do a search and find such things, hopefully.

What kind of counter are you using? If you're using a ripple counter
you're
going to have to latch the outputs to get rid of the glitch.

Yeah, I know it's a cb but it has a very large cabinet (aprox 11-1/2 W X 11-1/2 d X 5 1/2 H) that has that Collins look. That cabinet is in excellent shape and with a new front (blank) panel you could build anything you want in it. I guess it could be rebuilt and sold to a collector but the power transformer is out and I don't know what else, so would not recommend this. If you need a neat cabinet for a project or happen to have access to a not so nice looking FS-23 that's otherwise re buildable this might interest you. If interested e-mail me.

PS, I also have a steel hinged top cabinet (less front panel) probably from the 50's. It's in the attic put am guessing it to be about 11 -12 inches square. If interested I'll crawl up there (woe is me) and get it down and give you more specific measurements.

Check out :

http://www.cadsoftusa.com/

Their "Eagle" is availabel in a freeware version that would be quite useful
for most ham applications ... there is a limit on the number of layers,
etc.,
but otherwise, it's fully functional. (not too many hams make multi-layer
PCBs, so the limitations are essentially irrelevant, I believe.)

Not affiliated with them in any way, just a satisfied customer with their
"Professional" version ...

BTW ... there are versions for both Windows and Linux ...

969. Re: Determining SBL-1 Mixer LO Power level

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-02 00:00:00 UTC
From: William Janssen <billj@calweb.com>
Message-ID: <38987631.1738FD30@calweb.com>
Source record: 63574

Its been a long time since I thought about this problem but
as I remember it, a saturating core causes a pulsed output.
Transformers only have an output when the flux in the core is
changing. When the core saturates the output drops to zero.

I was using a 1/10 and a 1/16 counter - the glitch is enough to trigger one of the NAND's. I did pull out a Don Lancaster TTL book with a section on glitch removers (no section in his CMOS cookbook) - your right, a latch with a d-ff should work.

Merci bien, a bientot

Jack

Hello
I would like to get information on how to build a 2m tube amplifier with 2X
4CX250B or some other tubes
The amplifier should produce more than 500W on SSB
best regards Martin SM7VHS

Yes, from Ten-Tec. It is available as a 5w kit or with an optional higher power amplifier to build in. I have one and it works well.

976. RF Tank Circuit Question -- old VHF rig

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-03 00:00:00 UTC
From: JGinNY <jgovost1@twcny.rr.com>
Message-ID: <389A3874.F6F9C66A@twcny.rr.com>
Source record: 63448

Got an old tube-type VHF transciever for 50 Mc., circa. 1963 (Lafayette)

2E26 final amp, 15 W input

The TX output has a pi network tank circuit.
Also, there is a TVI trap on the output. This trap consists of a series L/C connected across the coax antenna jack. It is meant to resonate on TV channel 2, I believe.

Here's the ?:
Also connected across the antenna jack is a 1 K ohm resistor.
Is this part of the TVI trap, or what is the resistor's function?

Note this: At one point, I removed the L/C trap and the resistor from the rig. After I did this, the rig would not give _any_ RF output into an antenna. Zip. However, if I replaced the 6m antenna with a DUMMY LOAD, the RF amp loaded up fine and gave a very good output level. (Why would that make any difference?)

I reinstalled the 1 K resistor (leaving the L/C trap out) and lo and behold the amp would give a good RF output level again, both with a dummy load and with an actual antenna.

So...?? I have referenced numerous other transmitter circuits in older HANDBOOKS, using similar final tubes and output circuits, and none of them show any such resistance connected across the output. This should be really straightforward, but I'm not sure what is going on here.

Can anyone offer a possible explanation?

What stand are you using with the D-104, T-UG8 or T-UG9? The T-UG8 is a straight through connection and has a very high impedance off of the crystal which does need an impedance matching network. There was an article in QST early last year, around the February to May timeframe, about building such a circuit. If you have a T-UG9, it has a built in amplifier and an impedance around 5K. It matches very well as-is. In fact, I am using my T-UG9 with my Yaesu FT-757 GXII without any additional circuitry and it works great.

HI John -- in Dave Heil's Book "Heil Ham Radio Handbook" -- Melco Publihing -- P.O. Box 26 , Marissa Ill, 62257, he dicusses the problem of using a Hi Z Mic (D-104) into a low impedance mic input (many solid state rigs). He suggests using a 100K resistor or higher in series with the D-104 hot lead. And better yet (I suspect) is using a matching audio transformer. Some where I saw a UTC part for a matching transformer -- but don't know if they are in biz any more. Anyway you might explore these choices.

>I see Ramsey marked down their FX series 2m, 440, and 6m kits. Are they a
>good deal or a waste of money?

One day I found a Ramsey "Dual Tone Encoder - Decoder"
kit for $7.45. I thought that a good deal until I returned
home and discovered the kit consisted simply of a 567. It
can encode and/or decode only a single tone, no matter what
counting system one uses.
I figure that this was a relatively cheap lesson
regarding Ramsey's truth in labeling and the presumed
intelligence of their target market.

The hated Radio Shack still sells miniature impedance matching
transformers - I just bought one there a couple of weeks ago... They
work quite well between hi-low impedance loads.

Try: http://www.qsl.net/ei9gq/regen.html At the bottom of the page,
you will find links to some .wav files. I made these recordings to
show that it is possible to receive DX signals with a very
simple TRF receiver.

If these samples are not suitable, let me know what you need.

There are a couple of websites where you can remotely operate
a HFreceiver. Sorry! I can't remember the details.

Body handling: Binary attachment payload not displayed: atomski.vcf

Hello,
I'm sorry if this is off the topic, but I really need this info.
Does anyone have the COMPLETE info on amateur modes (modulations)
abreviations like J3E, F3C etc. I'd like to know which one is which.
Thank you in advance...

BDW does anyone have some plans for making a vertical omni-directional
antenna for 23cm? I want to use it on our ATV repeater...

Best regards de
YZ7REA Vladimir

See the diagram and a picture of it at:
http://home.netcom.com/~wa2ise/radios/dw117.jpg

It should also operate just fine on 220V and 100V.

100Volts, yes fine, it should work no hassles.

But unless the 100K resistors are big enough, no way on 220/240 volts. The current through the two 100K resistors and the four diodes will more than double, and the power dissipation will therefore quadruple. It's unlikely that the resistors were that much over-specced as to handle four times the power that the circuit would normally dissipate.

Rough calculations give a power of 0.3W dissipated by the two resistors. That's 0.15W each, and if they are 1/8 watt resistors (for small size), or even smaller, then that's too much power for their ratings.

Also, there will be at least 1.2mA passing through the 1n4148's, which is OK, since IIRC they're rated at something like 50mA.

You need to be careful in categorically stating that something that is designed for 110V should work fine on 240V when all their doing is using dropping resistors..

David.

998. WANT Tube HiFi or stereo amps: buying or ham & radio stuff to trade. ANY CONDITION

999. Raytheon CK722 and other early transistors question

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-04 00:00:00 UTC
From: Allan Pellnat <kx2h@worldnet.att.net>
Message-ID: <PoBm4.1322$Ks4.25961@bgtnsc06-news.ops.worldnet.att.net>
Source record: 63454
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I'm doing some research for an upcoming display of the history of the transistor and transistor radios for the AWA Electronic Communication Museum.

It seems that the general opinion is that the Raytheon CK722 transistor was the first mass produced for general consumption. However in poking around in some old Allied, Hudson, et al catalogs for 1953 I find some others listed. For example:

Allied Radio Catalog #131 for the year 1953, page 55, the first offering of transistors, lists 3 types available from either GE or Raytheon. GE G11 and G11A are Germanium Point Contact types. The only difference between them is that the G11A is □additionally tested for operation in trigger circuits□. Raytheon has a single type CK716 Germanium Point Contact.

Hudson Radio & TV Corp Catalog #H-53 for the year 1953, page 65 Shows same as Allied Radio #131. Same catalog, page 190 shows five types from Transistor Products Inc. They are Germanium Point Contact identified as types 2A, 2B, 2C, 2D and 2E.

Newark Electric Catalog #53 for the year 1953, page 65 Shows same as Allied Radio #131.

Then in 1954, Allied Radio Catalog #135 for the year 1954, page 63. Adds RCA to the manufacturers offering two Point Contact and two Junction types. The two GE types are the same as listed in 1953. Raytheon now lists three types. The CK716 is the same as in 1953 and two new types CK721 and CK722, Junction type transistors are added.

The following year, 1955, the CK716 was no longer listed.

So the question is who was first, GE, or Raytheon?

What happened to the CK716?

Allan Pellnat

Then again, maybe they were! (;>)

Actually, the total is half of that, so at 75 mW each, I think it's OK.

Gerry

CHAPTER I--FEDERAL COMMUNICATIONS COMMISSION
PART 2--FREQUENCY ALLOCATIONS AND RADIO TREATY MATTERS; GENERAL RULES AND REGULATIONS--Table of Contents
Subpart C--Emissions
Sec. 2.201 Emission, modulation, and transmission characteristics.
The following system of designating emission, modulation, and transmission characteristics shall be employed.
(a) Emissions are designated according to their classification and their necessary bandwidth.
(b) A minimum of three symbols are used to describe the basic characteristics of radio waves. Emissions are classified and symbolized according to the following characteristics:
(1) First symbol--type of modulation of the main character;
(2) Second symbol--nature of signal(s) modulating the main carrier;
(3) Third symbol--type of information to be transmitted.
Note: A fourth and fifth symbol are provided for additional information and are shown in Appendix 6, part A of the ITU Radio Regulations. Use of the fourth and fifth symbol is optional. Therefore, the symbols may be used as described in Appendix 6, but are not required by the Commission.
(c) First Symbol--types of modulation of the main carrier:
(1) Emission of an unmodulated carrier..... N
[[Page 521]]
~~~~~~

(2) Emission in which the main carrier is amplitude-modulated
(including cases where sub-carriers are angle-modulated):.....
--Double-sideband.....
A
--Single-sideband, full carrier.....
H
--Single-sideband, reduced or variable level carrier.....
R
--Single-sideband, suppressed carrier.....
J
--Independent sidebands.....
B
--Vestigial sideband.....
C
(3) Emission in which the main carrier is angle-modulated:.....
--Frequency modulation.....
F
--Phase modulation.....
G
Note: Whenever frequency modulation ``F'' is indicated, Phase
modulation ``G'' is also acceptable.
(4) Emission in which the main carrier is amplitude and angle-
D
modulated either simultaneously or in a pre-established sequence...
(5) Emission of pulses:\1\.....
--Sequence of unmodulated pulses.....
P
--A sequence of pulses:
--Modulated in amplitude.....
K
--Modulated in width/duration.....
L
--Modulated in position/phase.....
M
--In which the carrier is angle-modulated during the period of
Q
the pulse.....
--Which is a combination of the foregoing or is produced by
V
other means.....
(6) Cases not covered above, in which an emission consists of the
W
main carrier modulated, either simultaneously or in a pre-
established sequence, in a combination of two or more of the
following modes: amplitude, angle, pulse.....
(7) Cases not otherwise covered.....
X

\1\ Emissions where the main carrier is directly modulated by a
signal which has been coded into quantized form (e.g. pulse code

modulation) should be designated under (2) or (3).

(d) Second Symbol--nature of signal(s) modulating the main carrier:
(1) No modulating signal.....
0
(2) A single channel containing quantized or digital information
1
without the use of a modulating subcarrier, excluding time-
division muliplex.....
(3) A single channel containing quantized or digital information
2
with the use of a modulating sub-carrier, excluding time-division
multiplex.....
(4) A single channel containing analogue information.....
3
(5) Two or more channels containing quantized or digital
7
information.....
(6) Two or more channels containing analogue information.....
8
(7) Composite system with one or more channels containing
9
quantized or digital information, together with one or more
channels containing analogue information.....
(8) Cases not otherwise covered.....
X
(e) Third Symbol--type of information to be transmitted:\2\

\2\ In this context the word ``information'' does not include
information of a constant, unvarying nature such as is provided by
standard frequency emissions, continuous wave and pulse radars, etc.
(1) No information transmitted.....
N
(2) Telegraphy--for aural reception.....
A
(3) Telegraphy--for automatic reception.....
B
(4) Facsimile.....
C
(5) Data transmission, telemetry, telecommand.....
D
(6) Telephony (including sound broadcasting).....

These emission designations can be found in Title 47 of the Code of Federal Regulations, Section 2.201. This can be accessed directly in the USA. However, to
save you some long download time, I have attached the appropriate section below. Use a fixed width font to format this correctly.

TITLE 47--TELECOMMUNICATION
CHAPTER I--FEDERAL COMMUNICATIONS COMMISSION
PART 2--FREQUENCY ALLOCATIONS AND RADIO TREATY MATTERS:
GENERAL RULES AND REGULATIONS--Table of Contents
Subpart C--Emissions
Sec. 2.201 Emission, modulation, and transmission characteristics.
The following system of designating emission, modulation, and transmission characteristics shall be employed.
(a) Emissions are designated according to their classification and their necessary bandwidth.
(b) A minimum of three symbols are used to describe the basic characteristics of radio waves. Emissions are classified and symbolized according to the following characteristics:
(1) First symbol--type of modulation of the main character;
(2) Second symbol--nature of signal(s) modulating the main carrier;
(3) Third symbol--type of information to be transmitted.
Note: A fourth and fifth symbol are provided for additional information and are shown in Appendix 6, part A of the ITU Radio Regulations. Use of the fourth and fifth symbol is optional. Therefore, the symbols may be used as described in Appendix 6, but are not required by the Commission.
(c) First Symbol--types of modulation of the main carrier:

(1) Emission of an unmodulated carrier..... N
[Page 521]
(2) Emission in which the main carrier is amplitude-modulated
(including cases where sub-carriers are angle-modulated):.....
--Double-sideband.....
A
--Single-sideband, full carrier.....
H
--Single-sideband, reduced or variable level carrier.....
R
--Single-sideband, suppressed carrier.....
J
--Independent sidebands.....
B
--Vestigial sideband.....
C
(3) Emission in which the main carrier is angle-modulated:.....
--Frequency modulation.....
F
--Phase modulation.....
G
Note: Whenever frequency modulation "F'' is indicated, Phase
modulation "G'' is also acceptable.
(4) Emission in which the main carrier is amplitude and angle-
D
modulated either simultaneously or in a pre-established sequence...
(5) Emission of pulses:.....
--Sequence of unmodulated pulses.....
P
--A sequence of pulses:
--Modulated in amplitude.....
K
--Modulated in width/duration.....
L
--Modulated in position/phase.....
M
--In which the carrier is angle-modulated during the period of
Q
the pulse.....
--Which is a combination of the foregoing or is produced by
V
other means.....
(6) Cases not covered above, in which an emission consists of the
W
main carrier modulated, either simultaneously or in a pre-
established sequence, in a combination of two or more of the
following modes: amplitude, angle, pulse.....
(7) Cases not otherwise covered.....
X

Emissions where the main carrier is directly modulated by a
signal which has been coded into quantized form (e.g. pulse code
modulation) should be designated under (2) or (3).

(d) Second Symbol--nature of signal(s) modulating the main carrier:
(1) No modulating signal.....
0
(2) A single channel containing quantized or digital information
1
without the use of a modulating subcarrier, excluding time-
division muliplex.....
(3) A single channel containing quantized or digital information
2
with the use of a modulating sub-carrier, excluding time-division
multiplex.....
(4) A single channel containing analogue information.....
3
(5) Two or more channels containing quantized or digital
7
information.....
(6) Two or more channels containing analogue information.....
8
(7) Composite system with one or more channels containing
9
quantized or digital information, together with one or more
channels containing analogue information.....
(8) Cases not otherwise covered.....
X
(e) Third Symbol--type of information to be transmitted:

In this context the word "information'' does not include
information of a constant, unvarying nature such as is provided by
standard frequency emissions, continuous wave and pulse radars, etc.
(1) No information transmitted.....

TITLE 47--TELECOMMUNICATION
CHAPTER I--FEDERAL COMMUNICATIONS COMMISSION
PART 2--FREQUENCY ALLOCATIONS AND RADIO TREATY MATTERS:
GENERAL RULES AND REGULATIONS--Table of Contents
Subpart C--Emissions
Sec. 2.201 Emission, modulation, and transmission characteristics.
The following system of designating emission, modulation, and transmission characteristics shall be employed.
(a) Emissions are designated according to their classification and their necessary bandwidth.
(b) A minimum of three symbols are used to describe the basic characteristics of radio waves. Emissions are classified and symbolized according to the following characteristics:
(1) First symbol--type of modulation of the main character;
(2) Second symbol--nature of signal(s) modulating the main carrier;
(3) Third symbol--type of information to be transmitted.
Note: A fourth and fifth symbol are provided for additional information and are shown in Appendix 6, part A of the ITU Radio Regulations. Use of the fourth and fifth symbol is optional. Therefore, the symbols may be used as described in Appendix 6, but are not required by the Commission.
(c) First Symbol--types of modulation of the main carrier:

(1) Emission of an unmodulated carrier..... N
[Page 521]
(2) Emission in which the main carrier is amplitude-modulated
(including cases where sub-carriers are angle-modulated):.....
--Double-sideband.....
A
--Single-sideband, full carrier.....
H
--Single-sideband, reduced or variable level carrier.....
R
--Single-sideband, suppressed carrier.....
J
--Independent sidebands.....
B
--Vestigial sideband.....
C
(3) Emission in which the main carrier is angle-modulated:.....
--Frequency modulation.....
F
--Phase modulation.....
G
Note: Whenever frequency modulation "F'' is indicated, Phase
modulation "G'' is also acceptable.
(4) Emission in which the main carrier is amplitude and angle-
D
modulated either simultaneously or in a pre-established sequence...
(5) Emission of pulses:.....
--Sequence of unmodulated pulses.....
P
--A sequence of pulses:
--Modulated in amplitude.....
K
--Modulated in width/duration.....
L
--Modulated in position/phase.....
M
--In which the carrier is angle-modulated during the period of
Q
the pulse.....
--Which is a combination of the foregoing or is produced by
V
other means.....
(6) Cases not covered above, in which an emission consists of the
W
main carrier modulated, either simultaneously or in a pre-
established sequence, in a combination of two or more of the
following modes: amplitude, angle, pulse.....
(7) Cases not otherwise covered.....
X

Emissions where the main carrier is directly modulated by a
signal which has been coded into quantized form (e.g. pulse code
modulation) should be designated under (2) or (3).

(d) Second Symbol--nature of signal(s) modulating the main carrier:
(1) No modulating signal.....
0
(2) A single channel containing quantized or digital information
1
without the use of a modulating subcarrier, excluding time-
division muliplex.....
(3) A single channel containing quantized or digital information
2
with the use of a modulating sub-carrier, excluding time-division
multiplex.....
(4) A single channel containing analogue information.....
3
(5) Two or more channels containing quantized or digital
7
information.....
(6) Two or more channels containing analogue information.....
8
(7) Composite system with one or more channels containing
9
quantized or digital information, together with one or more
channels containing analogue information.....
(8) Cases not otherwise covered.....

It appears that a dc path is required through the load for operation. Check the diagram to see why; perhaps it's needed for some kind of feedback or something.

It's wise to have a dc path in any case to prevent high potential static buildup. But why the radio won't transmit without it requires looking at the diagram.

As a teenager at the time price was a consideration for me. Raytheon's CK722 was $.99. Another affordable transistor at the time was the GE 2N107 which was a little more at $1.25. Used to ride my bicycle to Henry Radio to get them. That's when Henry Radio was a COOL place.

I have bought a secondhand grid dipper: ALTAI KDM-6. But unfortunately it down't dip (okay, I'm ready for all your jokes!). The thing is it does oscillate, I can check that with a receiver. But when trying to use it as a dipper the needle doen't move at all. Can anybody suggest what tests to perform to find the prolem? OR does anybody have the circuit diagram for this dipper?

Thnaks, Hubert

I've no problems putting 1W into 1/4W resistors, even for a long time,
provided the applied voltage is clean.
Don't do this if you plan to run a 100K production of your design, though
:-)

I missed the original post, but from the subject I guess you want to run a
low-voltage (5V?), low-power (5mA?) device directly from the powerline. Why
not using a capacitor instead of the series resistor(s)? It dissipates
virtually no power.

There was an article in QST a few months ago on matching the D104 to the new low impedance radios.

HI John -- in Dave Heil's Book "Heil Ham Radio Handbook" -- Melco Publihing --
P.O. Box 26 , Marissa Ill, 62257, he dicusses the problem of using a Hi Z Mic
(D-104) into a low impedance mic input (many solid state rigs). He suggests using a
100K resistor or higher in series with the D-104 hot lead. And better yet (I suspect) is using a matching audio transformer. Some where I saw a UTC part for a
matching transformer -- but don't know if they are in biz any more. Anyway you
might explore these choices.

Keep those LollyPops speaking

The GT-34 was also affordable at $.99. I was getting $0.50 per week allowance. I used some of each for audio amplifiers. The GT-34 generally had higher gain. I had to ride six miles by bike to get parts (Electronic City at Mid- Island Plazza or Electronic City (store name?) at Rosevelt Field Shopping Center) or wait to Saturday and take the bus to go to Hempstead at Standard Parts. Once in a while you could get wet slug tantalum caps (Mallory) at charity prices (100 piece prices) from Rosevelt Field Shopping Center store. This was about 1954,1955 and I was 12 years old. All this was on Long Island.

Gee, guys ... it's nice to see the nice comments on the AT&T 9520 phone.

I am proud to say that I one of the principal architects of the chipset that
makes it work :-) I also designed the all-digital FSK modem therein which
helps it get such good range (the modem performs within about 1 dB
of theoretical ideal). Another thing that helps the system get such good
range is that it uses Reed-Solomon Forward Error Correction (done in
software) to help extend the range by fixing bits that are received in error
as you get near what would otherwise be "end of range" ... that keeps the
sound quality better farther out ... to the best of my knowledge its the
first
use of FEC in a consumer cordless phone ... you might also be interested
to know that both the handset and the base contain low-power 100 MIPS
DSP processors, as well as a mixed-signal ASIC and a single-chip RF
transceiver.

The guys in the Lucent Comsumer Products division who designed
the phone around the chipset did a very nice job of making an
attractive phone and getting all the performance the chipset was
designed to deliver.

However, I would recommend against attempting to modify the
phone to add external or extended antennas ... that would invalidate
the FCC Approval ...

hi,

Iwas planning on building a VCO using a NE602 as VCO + doubler.
Ne602 will certainly operate at this freq, and there is a phillips appnote
that covers the use of NE602 as a doubler.

Roger lascelles wrote:

>what is your idea ?

It would help us if you'd have provided some of the details on whatever the heck a CFS455 is! (Dig, dig, dig). Looks like you're talking about a Murata rectangular can filter. Specs seem ok. The datasheet for the '3359 says that the IF filter impedances are in the range of 1.5k to 2k ohms. Come to think of it, I've a couple of receivers (a scanner and and a "baby monitor") that use the Murata type IF filter with the MC3361.

I did a FM SCA decoder using the '3359 using the Toko HCFM-2455x series (where x = A-E or thereabouts) and found that it was fairly tolerant and had so much gain that just about anything worked. The Toko parts are nice because they're a 3 pin part with .1 inch spacing that matches the pinout of the chip and can have very short connections.

The mixer in the chip isn't anything to write home about overload wise, (neither is the NE602, reportedly) probably a function of the high gain in the whole chip. If you're going for performance, a filter at the first IF before the '3359 will get you more improvement than putting more bucks in the 455 kHz IF filter.

Yes, this is a wicked phone. I own one too, and when it is transmitting on the edge of its range, at 220 mW, it actually gets warm to the touch after a while. And, obviously goes through the battery in a hurry. As you move in closer to the base, it trottles down, and battery life becomes more normal. I routinely get about three hours of talk time, within my appartment. The fact that it fully recharges in four hours, doesn't hurt either.

I read a review of this phone, and the fellow said that it has the greatest range of any 900 MHz or 2.4 GHz phone that he has ever tested.

My experience backs this up as well. I live in the city, and the range is impressive. It would not surprise me if this phone were to actually achieve more than two miles in open country, and that's without any antenna help.

1028. Re: RF Tank Circuit Question -- old VHF rig

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-05 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <87fq0r$98b$1@plutonium.btinternet.com>
Source record: 63483

A relatively high value resistor which apparently serves no useful purpose at RF is often there to DC ground parts of the circuit which would otherwise be floating and acquire a high charge. A resistor is cheaper than a choke if the small RF loss can be tolerated.

Any DC current flowing through the resistor may be used somewhere else in the circuit, perhaps in another piece of equipment. Does any current flow through it ?

The series LC anti-TV trap may not now serve a useful purpose. However its removal may de-tune the tank or pi-match circuitry.

1029. Re: Problems with Altai dipper

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-05 00:00:00 UTC

Source record: 63484

Hi,

Three points - if your dipper has a control for the meter level,
make sure that it isn't set too high as this will often mask the dip
(this is very true for LCR bridges also); ensure that the dipper and
tuned-circuit coils are as parallel to each other as you can get them
and make sure you know the approximate resonant frequency of the
circuit you are checking first.

Transistorised dippers in my experience are not as good as the old
tube types. I seem to remember Millen doing an article years ago (QST?)
on the design of such a dipper which was very informative.

Probably should have said to use a pair of 220K resistors in place of the
100K's when using it on 220VAC. That should work. A reason for the
resistors on both legs of the line is to minimize shock hazard current
if a grounded person should touch bare metal in the watch module. My
watch is completely encased in plastic, no exposed metal.

> if a grounded person should touch bare metal in the watch module. My
> watch is completely encased in plastic, no exposed metal.

The whole concept is of course flawed when it comes to safety. If one of
the resistors should fail short (and it does happen), then the whole watch

risks going live. Regardless of whether the thing is enclosed in plastic or not, I bet the insulation is not spec'ced to handle full mains potential from anywhere inside to anywhere outside. It would never pass UL or other safety testing. I therefore suspect it is not a commercial design. Also, the resistors would have to be special high voltage types, since most are only rated at 100V DC (which isn't the same as 100VAC at all!).

If that is the case, then the originator of the design is committing a gross act of negligence by not having a large warning displayed on all material promoting the "design". This warning should contain wording containing something like "the entire watch should not be touched or exposed to humid environments while under mains power, as the entire device may carry full mains voltages." To do any less is inviting disaster at inexperienced hands. More would be better.

In all, it's a cute idea, but if not done properly is worse than dangerous. A minimum level of responsibility must be taken when dealing with mains. That's why there's standards around.

David.

1033. OE5DXL 9k6 modem for PC/Atari ST

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-05 00:00:00 UTC
From: Chris <nibbit@wanadoo.nl>
Message-ID: <87gm1c$1cu8$1@buty.wanadoo.nl>
Source record: 63488

Hello,

if you are interested into using 9k6 packet, but not want to spend to much, maybe this modem is interesting for you.

Hardware & software are develloped by Chris - OE5DXL and is available for Atari ST or PC.

one thing: the L2PCX/L2STX driver only supports hostmode prgs. (ie. SP)

I build the Atari version, and after it worked i have sold my expensive 9k6 TNC ;-) (my modem costed me only 10$)

My website: http://www.qsl.net/pe1nib/

I don't have any experience with the PC version (since my Atari still works great:-)
so if you want to share your experience about the PC version (L2PCX) let me know (pe1nib@qsl.net)

73's Chris de pe1nib

What you think of idea of realization of radioexpedition on Southern Altai?

Southern Altai - highland is on the board of Kazakhstan, Russia, China and Mongoly.
Land of lakes and waterfalls, mountain taiga and stormy rivers, deserts and snowy peaks...
In time of Soviet Union this territory had been absolutelly inaccessible for foreign tourists (and furthermore for radioexpedition) - in locale
It is not enough of ham stations.

The base camp of expedition is planned to place in region by highest Fastigiums of Siberia and Altai of a mountain Belooha, lake Markakol and Zaisan.

If you were interested by our proposal, we can be found on ranges 21Mhz, 28Mhz call sign UN8JZZ (collective radio station)

1038. 50-100 Mhz receiver?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-05 00:00:00 UTC
From: Matt <mattj@flashmail.com>
Message-ID: <389C1725.A6A03182@flashmail.com>
Source record: 63493

Hi all.

I'd appreciate any suggestions on how to go about constructing a 50-100Mhz receiver, with a direct output ie no demodulation. I want to keep it as simple as possible, though I want to be able to pick up fairly faint signals. Would it be feasible to modify a small FM radio receiver?

Thanks,
Matt.

need a 12dB amplifier, possibly high IP and a divide by 4 hybrid,
consisting of 5 equal resistors, value 30 ohm, 33 ohm will work well

The amplifier may use a 2N3866 or BFR96. Have a circuit for 14dB
broadband amplifier (1-30MHz) with 2N3866 just tested, also tested a
BFR96 amplifier, this has 15dB gain, was found in QST, but such
circuits are shown in W7ZOI/W1FB's book "Solid state design manual"

my circuits are available as gif files. With 0.1uF capacitors they
will work down below 200kHz, I modified them for use as pre-amps for
136/1800kHz receiption, with 0/10/20dB attenuator

The problem using 50 ohm amplifier with the simple divider is that
unused outputs must be terminated (47 ohm resistor).

I have talked to Ray Waugh of Agilent about this app. note and he
said that PIN diodes of a certain type of construction can act like
step recovery diodes, and that the aforementioned diode has the
correct type of construction. Thus there may exist some other PIN
diodes which also work as SRD's, but it is not true in general that
PIN diodes can be used this way.

1044. IRF511 Gate Charge

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-05 00:00:00 UTC
From: wandrangus@aol.com
Message-ID: <20000205141029.20978.00003010@ng-cg1.aol.com>
Source record: 63499

About 10 years ago I designed a QRP transmitter for an IRF511 MOSFET, which could deliver 2W on 40M at better than 80% efficiency. I recently built one up according to my old schematic, and found that it didn't work very well. Checking, I found that the gate charge on new IRF511 MOSFETs was significantly higher than that on old, 1980's dated ones, which reduced their gain. Both were IR MOSFETs..

Anyone else noticed this? Anyone know how the new parts differ from the old ones? Is there an equivalent part with improved gate charge? I don't have a whole lot of old IRF511's left in my junk box!

Thanks!

Basically yes,
It would be easiest if you choose something that has the frequency range
you want, so lets assume that you have such a beast.

Most receivers only get rid of the received signal at the demodulator at
the end of the IF stage so at best you can take the output of the last
IF or maybe the one prior to that. This should give you the received
signal at the IF frequency, you can the do what you like with it by
feeding it through a small buffer amplifier and then hanging whatever
you want off the end.

If you can't get a set that covers these bands then get the closest
match and you will have to vary the VFO to run over the frequencies that
you want, this could be cumbersome and complicated but is essentially
feasible.

Hope this helps

Robin

I had this problem with a different make. I replaced the wheel with a copper loaded carbon brush which sits on the wire. You need access to a milling machine to make it fit but you then have multiple contact with the coil and carbon is self lubricating. You may lose a millewatt or so in the brush!!!

Good luck.

Between the plate of the tube(s) and the tank circuit there should be a DC blocking cap. The resistor is there to give a 0V DC reference to the RF output, to drain off any static that might be fed in from the antenna, and to blow the B+ fuse in case the DC blocking cap shorts out, otherwise such a failure would cause a safety hazard (live B+ to the antenna and feed line.)

>Note this: At one point, I removed the L/C trap and the resistor from

>would that make any difference?)

Well if exactly the same radio will feed just fine into the dummy load, but not into your antenna, then your antenna and feed line must not look like 50 Ohms. Check them out.

My advice is to use two plastic prongs if you insist on plugging in to an AC outlet. Then let the internal battery do its intended function. Change the battery every few years, when needed.

Otherwise, a nail sticking out the back will attach it to a wall, without a wall outlet.

Besides, AC outlets are often (intentionally) placed in inconspicuous places. Not the place to keep a clock.

The latest QEX (Jan iI believe)from arrl has a low phase noise 0->250
mhz DDS controlled signal generator in it. It looks like a nice quality
setup, but it will cost a bit to reproduce.

Hi,

I'd like to buy following variable capacitor made by " COMET "
These variable capacitors are used in RF matching network.

(1) CV05C-1000W/5 , 10 - 1000pF 5KV/3KV

(2) CV1C - 500W/15 , 12-500pF 15KV/9KV

Since I'm not familiar with variable capacitor , I don't understand the
above spec. I'd like to know where I can buy this .

I apprecaite your information so much.

Hi, I have a Fluke 87 (about 8years old). When I went to use it today it gave me a value of 1 volt dc with the leads shorted. Also the leftmost digit flickers between 1 and 0 on all settings except Ohms.

Any suggestions? Anyone have a schematic or know where I can get more info? Thanks a bunch, Art.

Assume the antenna is 50 ohms at RF, but an open circuit at DC.
The dummy load is probably just a resistor, and is 50 ohms at both RF and DC.

So it seems likely that the DC path is necessary for proper operation.

1070. Re: Ramsey Kits: to buy or not to buy?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-07 00:00:00 UTC
From: Sam Brutcher <sbrutcher@fallschurch.esys.com>
Message-ID: <87n3m5$epa5@fcserv3.fcd.esys.com>
Source record: 63525

I tried Ramsey kits when I first got my license. They're well-packaged and easy to build, with very clear instruction manuals. Also relatively cheap.

Specifically, I thought I'd get started with their 40m DC receiver kit and 40m transmitter. The transmitter worked great, but I never did get the receiver running properly. Now I'm not sure DC is the way to go for a beginner. I ended up getting a 30m superhet kit from the Small Parts Center (now defunct) along with a multi-band module for 40, 15, and 10 meters. It worked perfectly the first time, and this was only my third kit!

Then I picked up a Ramsey keyer and "touch-control" paddle kit at a hamfest. The keyer worked - sort of. The paddle gizmo - which used two pieces of copper-clad in lieu of moveable paddles - was totally useless. I ended up getting a used keyer and paddles at a local ham shop. Perfect.

Later, for some reason, I tried out the Ramsey low-power FM transmitter. It worked as advertised, but the older version I had was really unstable. Very bad frequency drift.

My last experience with a Ramsey kit was their Van de Graaf generator. Not recommended. It works - sort of.

Generally, I've had much better luck with a mixture of kits from other manufacturers and used components. Ramsey kits are fun for a beginner to play around with, but I would NOT recommend them as reliable, full-time amateur radio equipment. If you have kids or ARE a kid, go for it. Otherwise, I'd suggest Ten-Tec, Dan's Small Parts, Kanga, and other QRP kit manufacturers. Their kits are of much higher quality and usually work better. Just search the internet for "QRP" and see what you can come up with.

Good luck!

Go to the Fluke web site and request information there. But I am guessing it's not worth repairing; it's possible that the main integrated circuit has failed.

On the other hand, there is a fuse/resistor to protect the input. If that opens you might get symptoms such as you indicate. Fluke also has a toll free number for technical support and they might steer you to a fix.

Most multicouplers I have seen pretty much suck bilge water as far as I am concerned. By there nature they have to be broad banded are a poor substitute for the front end of most decently designed receivers. I understand that you have to do what you have to do and the multicouplers may be your answer but perhaps you may want to consider other alternatives such as separate antennas or just a passive splitter.

Anyone running a Tek 490-, 2700-, or 7L-series spectrum analyzer may wish to check http://www.qsl.net/ke5fx/tr503.html. I've just finished updating the page with details on a relatively-inexpensive tracking generator project covering near DC to 1.8 GHz.

The design is somewhat dependent on having a well-stocked junk box, but there's a lot of room for flexibility in component selection. As with everything else on the site, comments and feedback are always appreciated...

If the DC blocking cap was leaky, and this led to the final tank and
antenna charging up to high voltage and arcing over, then the loading
would indeed be impossible while something was arcing.

Other than that, any DC voltage is irrelevant to the RF matching.

Go to www.aade.com; Niel Heckt has a very good program, that will not only do what you need, but it will also synthesize filters that have unequal input and output impedances. I have used his program for about a year, and it has been great! You get to use 10 times, before you have to make a decision to purchase it for about 30 dollars. Give it a shot, and you will not be dissapointed.

I'm assuming you changed the battery, and checked the fuses inside...

Have you contacted Fluke? My 87 had a malfunction about two years ago (eating batteries like crazy), and when I submitted it to the Fluke Service Center in Dallas for repair, they allowed as how their equipment is now waranted for life. They repaired it by swapping out the main board, placed a NIST-traceable calibration sticker on it, all free except shipping.

Worth a call...

Good luck,
monty N5FC

Does anyone know of shareware rf filter design programs?

I need a program that can do band-pass, cheb, high pass, low pass etc
for lumped element designs from about 1MHz through about 0.5GHz

I had a couple programs that worked well that I got from RF design,
about 8 yrs ago. I have misplaced the 5 1/2" floppies. They were
excellent.

Thanks

Steve

Dear Gentlemen:

I have this little system, and I want to put it a 5/8 element.
Does anyone know what is going to be the matching device for best performance?
And is there any general formula function of frequency, that is going to

give me Henrys and/or Farads for this?
Thanks.

Oh, get a clue. You're bitching to an automated mail list gateway.

The amateur radio newsgroups have always been gatewayed back and forth across to their mailing list equivalents. Sometimes there's a problem when a mail server bounces a message for some recipient that's no longer there or has other problems. Some people can't get the newsgroups, so e-mail is the only way they can particpate. These mailing lists have been around since the Arpanet days, which makes these groups/lists some of the longest running discussion groups around.

These products started out as a way to offer homebrew projects to the disabled and senior citizen ham who wasn't able to "roll their own". Since then, many people have purchased the devices because of their uniqueness and inexpensive price.

While you are replacing the batteries, connect a clip lead across the
meter's battery leads with the batteries vacant. This may help to discharge
electrolytic caps that may keep enough voltage on the uP that keep it insane.
I have used this trick successfully several times with consumer goods.

[symptoms deleted]

Send it to Fluke, and they will fix it. The meter has a lifetime warranty, and repairs are free unless you obviously abused it -- I had to pay for my Fluke 77 repairs after I put a non-current-limited 1500VAC across it. But the repairs were a lot cheaper than a replacement.

If you find a used but busted Fluke meter for cheap, it might be worth your time to buy it and send it to Fluke for repair. A lot of owners don't know this.

for what you would pay for a ramsey hit you can buy a tentec kit i have had both and the tentec is a better kit not only that tech support for ramsey (1 to 10)is about a 3, on the other hand tentec is about a 8. I wouldn't go with a ramsey in my own words ramsey is made from jumk (mfj) Ramsey 2 meter kits is about 100.00 give or take a few $ A TENTEC is only a few dollors more. tentec you get a led read out (frz.) ramsey you don't,tentec you get mem....ch. without reprogramming the rig ramsey you don't, tentec you get 10wts. or 25wts. or both, ramsey you only get 5 watts.with a few more $ you get a hold lot more for the money going with tentec and a real good tech support, with ramsey don't even try to talk to tech support i thank they are asshold!!!

Hey Grant, a good rule of thumb method of testing your coax is to put a signal down it into a dummy load and run a field strength meter along it , any breaks in the shielding etc will show up instantly!

Message-ID: <87sj3v$25j$1@bbs.aeminium.pt>
Source record: 63410

Hello,
i have one of these radios a friend of mine gave me
a couple of years ago and now i'm planning to convert it to 2m
operation.

I searched the net and found at

http://www.morgan2.demon.co.uk/files.html

a program called midland.zip which enables you to program the
27C16 EPROM of this radio. Does it work fine? I need to
desolder the EPROM, that i'm planning to do it today, and
searched the net for the radio IC's with not much luck...

Any of you done the same? Tips, ideas, max channels allowed,
frequency range, max power, etc are welcome! The radio
schematic would be great, do you know were can i find it?
I couldn't find the Midland HomePage!

Thank you,
Nuno Sucena

1106. 7-seg LCD source?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-09 00:00:00 UTC
From: Michael Tracy <kc1sx@arrl.org>
Message-ID: <KZzo4.11$UT2.6907@news.ntplx.net>
Source record: 63411

Does anyone know of a source for 7-segment LCDs? Multiple digits are fine, I just don't want to be bothered with the extra baggage dot matrix displays involve. I would also prefer to not rip apart an existing device (such as a clock) because I want to have a project others can duplicate.

I will fall back to LEDs if need be, but would prefer a source for LCDs. So far, I've looked through every catalog and web page I could find with no luck. All the 7-seg LCDs come wrapped up as panel meters, up counters, etc.

I could use an up/dn counter too (that's what I really want anyway), but nobody seems to make any of those either.

Thanks and 73, Michael Tracy, KC1SX

You may want to try "http://www.allied.avnet.com". They have
7-segment LCD panel displays in a variety of configurations,
from 2 to 8 digits. The manufacturer is AND and is on page 632.
I did a search as follows:

Search Criteria: LCD
Search Scope: Part Description
Limit & Refine Search: LCDs, LEDs, Lamps & Sockets

You shoud get about 77 hits and you will have to scroll through
the pages. The part number for the 7-segment devices starts
with "FE".

> I could use an up/dn counter too (that's what I really want
> anyway), but nobody seems to make any of those either.
>

You didn't say whether you want a binary or BCD counter or
what technology (ls, hct, ac, cmos, etc.). The most common up/dn
counter, that I know of is the 74ls191, but that's a binary
counter.

Fairchild makes a CD4029BCN Up/Down counter that is Binary/BCD.

TI has a CD74HC192E Synchronous BCD Decade Up/Down Counter

There are several more, all accessable from the same web address
mentioned above. I just did a "Part Description" search using
"Up/Down Counter".

hi! michael,
you can buy 7 segment lcd displays from maplin electronics www.maplin.co.uk
they have a few models to choose from.

hope this helps.

luis

Source record: 63420

Dave, the first knowledge I have of use of PC inductors was in the Tektronix 453 oscilloscope. I have one of those but am loath to open it since it works great.

Stability? Well I think it's pretty much limited by the temperature coefficients of expansion of the materials, so that a proper proportioning of the inductor could result in good stability. In other words, an increase in size would result in no change of inductance. You might have to be clever to accomplish it.

This assumes the materials are isotropic, pretty reasonable for stuff like epoxy filled fiberglass.

Do outfits like Coilcraft make PC inductors, or are they limited to wire designs?

See Terman's handbook for inductance of a straight wire; there is a graph. You can see how wire diameter and length affect inductance, and thus there is probably a ratio of the two that would maintain a constant value over a reasonable range of temperature. Probably some playing around with terminations would have a lot of effect too.

I wish I had some practical experience to share but I don't.

I've used PC inductors and PC spark gaps for RFI and EMI control. For small, non critical values, they work quite well and are cheaper than ferrite beads. Another technique I've used is a PC inductor with a ferrite disc cemented to the PC on the opposite side. I tried making a VHF preamp once with PC inductors, and ferrite slugs mounted in tubes glued above the inductors for adjusting. It worked, but the Q wasn't quite as good as a regular coil, possibly because of the necessity of having a wire jumper to make contact with the inner end of the spiral. (single-sided board) Fertile ground for experiment though.

I have made such a project long ago, at that time I used a vic-20 to handle the hardware, as it was already watching other hardware. It was connected to my pc with the serial port.
If I was going to make something today, I would use the printer port on the pc to read the dtmf decoder.
If your printer port is at all modern, it should support 8 input/output lines, plenty for the 4 or 5 bit info you want to read.

I've been getting SMT Rs, Cs, Ls, Qs, Ds and Us (that last one is ICs, both digital and analog...In digital, it's ranged from PIC microcontrollers to 74AC-series logic to Xilinx CPLDs) from DigiKey and from Mouser here in the US, for my hobby work. I've even gotten fuses and PTCs in SMT. Considering how large a percentage of new commercial designs use SMT, I'd be surprised if other similar suppliers in other parts of the world didn't stock them as well.

Cheers,
Tom

QCad might be what you are looking for. It is free open-source
software that runs on Linux. I haven't tried it yet myself, so
can't give any input on how well it works. It's just in my
bookmarks file as something to check out some day when I need it.

Go to http://www.qcad.org. Be careful to put in the "org".
qcad.com is somebody else.

1142. FS: capacitors, tubes, sockets, sweeps, vacuum relays, MORE...

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-11 00:00:00 UTC
From: ovrreactor@aol.com-nospam
Message-ID: <20000211183626.22406.00003169@ng-fh1.aol.com>
Source record: 63354

I've moved my "Tom's Online Garage Sale". I merged it with one of my "other" websites. There's a ton of stuff that I'm selling, like capacitors, tubes, sockets, vacuum relays, and tons of other stuff that I just don't have room for. Go to;

http://members.aol.com/ecc81

Also, I listed a whole bunch of capacitors on eBay last weekend. No reserve, most opening bids are $0.50 for the entire lot, some of them have opening bids of $0.01, just because I WANT MY GARAGE BACK! Auctions close this weekend (some Saturday, some Sunday)! To see the whole list, go to;

http://cgi3.ebay.com/aw-cgi/eBayISAPI.dll?ViewListedItems&userid=over-reactor

Here are the lots that I'm auctioning off;

(40) 1800 uF 16 V axial capacitors
(75) 2000 uF 12 V General Instruments axial capacitors
(120) 175 uF 15 V axial capacitors
(2700) 5 uF 12 V General Instruments axial capacitors
(100) 150 uF 25 V axial capacitors
(75) 10 uF 10 V non-polar axial capacitors
(100) 150 uF 35 V RCA/Mallory radial capacitors
(40) 1800 uF 16 V axial capacitors
(200) 33 uF 16 V radial capacitors
(100) 68 uF 16 V Elna radial capacitors
(100) 1200 uF 20 V radial capacitors
(425) 47 uF 40 V radial capacitors
(120) 47 uF 16 V radial capacitors
(300) 150 uF 15 V RCA/Mallory radial capacitors
(75) 200 uF 6 V Ducati axial capacitors
(150) 5 uF 3 V non-polar General Instruments axial capacitors
(75) 50 uF 20 V General Instruments axial capacitors
(50) 30 uF 60 V Mallory axial capacitors
(190) 330 uF 16 V Nichicon axial capacitors
(125) 220 uF 16 V ICC axial capacitors
(75) 20 uF 100 V Mallory axial capacitors
(350) 25 uF 10 V radial capacitors
(150) 25 uF 15 V axial capacitors
(44) 100 uF 63 V United Chemi-con radial capacitors
(90) 10 uF 25 V axial capacitors
(100) 22 uF 35 V radial capacitors
(240) 25 uF 3 V Ducati axial capacitors
(400) 200 uF 6 V axial capacitors
(600) 25 uF 15 V Mallory radial capacitors
(180) 100 uF 15 V Mallory axial capacitors

I've been away from building for awhile and it seems Lafayette, Knight, Allied and the others have evaporated. Rat Shak doesn't supply enough to build a GDO coil. Where do you guys buy your components these days? I tried to get some simple stuff: a 250 Ohm carbon pot, a 10 Ohm resistor and a 1000 picofarad capacitor. I might as well try to get anti-matter crystals for the Enterprise! Surely there is one supplier left???? TNX, Johnny

All I can say is, you must not have been looking very hard.

http://www.radioshack.com actually has a very respectable stock of components, including everything you mentioned (although you'll have to settle for a 200-ohm pot). Next time you're in a Radio Shack store, pick up one of the new commercial catalogs -- it makes a good pictorial index for their site.

http://www.digikey.com, http://www.newark.com, http://www.mouser.com, http://www.jameco.com, and http://www.web-tronics.com/ carry just about everything Radio Shack doesn't.

There are any number of specialized RF- and microwave-specific parts vendors on the net as well, including http://www.minicircuits.com, http://www.downeastmicrowave.com, http://www.shfmicro.com, and http://www.fix.net/dans.html. Some of the smaller outfits have some really annoying policies, such as no way to place credit-card orders on their site, but they're still darned nice to have on your bookmark list.

Then there is eBay. The "Electronic Parts" category on eBay gets a little better-populated every day:
http://listings.ebay.com/aw/listings/list/category4659/index.html

Take a closer look at some of these sources, and you won't miss Lafayette and Allied much at all.

1150. Re: Printed Circuit Inductor

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-11 00:00:00 UTC
From: wb4lnm@aol.com
Message-ID: <20000210200200.24980.00002561@ng-ci1.aol.com>
Source record: 63441

Several commercial land mobile radio manufacturers have used printed inductors on FR-4 style printed wiring boards as tuning elements on their UHF (470 MHz) VCO's. Since the VCO as part of a synthesizer can somewhat tune out small, long term deviations in inductance (like those caused by temperature variations), it is an appropriate application. I also have a GE MASTRII transceiver here in the house that uses spiral printed inductors on its boards, although at the moment I don't know in what stage without looking at the manual.

There have been articles published on designing these, but most of them that I have access to would date back to the mid to late 1970's (not that the physics change). These coils are very repeatable in manufacture and are practical in certain applications. Just like anything else, there is a cost versus performance tradeoff. They will certainly not compete with a Kovar cavity for Q, volume or cost. Knowing what the application was for your friends need (oscillator element, filtering, etc.) and what frequency under what environmental conditions and cost constraints and manufacturing quantity would determine if a printed coil is a likely candidate.

Hi,

I am looking to construct, as a learning project, an off-air frequency standard using one of the UK transmitters such as Droitwich (198kHz) or MSF (60kHz) and thus condition an oscillator ï¿½ la W5OJM's GPS-based design or my own version thereof. I would appreciate any thoughts you folks might have on this and pointers to any sites having information especially that on problems due to the vagaries of propagation in the LF/MF regions. This type of thing has been done before, I know, but I just want to play :-)

Thanks in advance.

Bob,
According to one response, it's a Radiola 25. I've been trying to
find another picture but have come up empty.
I acquired it at an auction (it was in a box with other stuff)
It does have a coil, about 2 inches in diameter...3/8 inch high.

Thanks for the repsonse,
Mark

>good deal or a waste of money?

Since I did buy their 2m kit, found many of its problems, debugged them, and came up with modifications to make it at least legal if not actually clean, I can confidently say, buy something else unless you're trying to sharpen your debugging and redesign skills, and have sufficient test equipment to do so. At minimum, a spectrum analyzer and a good calibrated signal generator are necessary to debug the radio's problems and confirm that your modifications fix them.

The FX series manual is exhaustive, in some senses a cut above what most of the others provide, but the basic radio design is flawed. If you follow the manual's tune up procedures, you'll have a comb generator instead of a clean transmitter. Receive sensitivity will be wretched, you'll have a sweeping spur across the band when you go from receive to transmit, there's a nasty *thump* in the audio. etc. You *can* fix all of these problems, but it does require some redesign.

OTOH TenTec kits are generally excellent. Kanga offers some good kits. There are a number of others. Most of these will work correctly if you build them and tune them up according to the instructions. Ramsey is not in their league.

Gee, you *have* been away for a while. :-)

>Rat Shak doesn't supply enough
>to build a GDO coil. Where do you guys buy your components these days?

My first impulse is to check Digikey (1-800-DIGIKEY) or www.digikey.com .
Digikey has a very large selection of parts, is rarely out of stock, accepts
orders either via phone or over the web, and has quick shipping. ($25
minimum order though)

My second impulse (quickly becoming my first impulse) is to check
RadioShack.com, formerly known as Tech America. They have a web
presence at www.radioshack.com . They have a large commercial
selection of parts (growing every day), and better for me, one of their
stocking warehouses is on my daily commute route so I can just drop
in and pick up what I need. No minimum order. (You can also order
through any Radio Shack store.)

Then of course there are the old standbys like Newark and the other
old line distributors. Most of them will sell to you, though they often
have a minimum order requirement varying from $25 to $100, and they
tend to put you on back order for the sorts of things you'd most expect
to be in stock. Just save up your needs until you exceed their minimum,
then wait for them to get around to shipping.

Also, many of the component manufacturers will sample you a part
or two for free. Just call and ask. Motorola has been very good to me,
as have Analog Devices and a number of other manufacturers. This
is one of the best ways for an amateur to get hot new parts.

And if you *really* want to save money on a 5-watt 2m rig,
radioshack.com has an Alinco DJ-190TD handheld in their February flyer
for $99.95 (case, speaker mike and rubber duck antenna included).

This is also my experience. The kits are nicely documented, but full of
engineering errors. Easily fixed, but that's not why most of us buy kits--
at least I don't.

I got it $10 cheaper when they were selling them at a local hamfest.
Note that the alkaline battery case that comes on it is a piece of crap.
It doesn't have enough contact pressure for the AA battery terminals,
and the pack voltage will sag below the radio's low voltage cutoff while
transmitting, even though the batteries still have lots of life left, due
to the voltage drop across the contact resistance.

This is a pack design defect and I haven't found a good easy way
to increase the contact pressure, so I just use it off an external power
source (barrel connector at side of radio run to a cheap camcorder
gell cell). There is an optional Nicad pack that works Ok, but it is
pretty dear for such a cheap radio. Note too that there is no TT pad.
The DJ195 comes with the Nicad pack and has a TT pad standard,
so it may be a better buy.

Gripes about batteries aside, this is a pretty decent full power basic
HT at a pretty good price. Audio quality is good, intermod resistance is
better than many higher priced radios, etc. I use it as the uplink radio
for my portable AO27 satellite station, and for packet (1200 baud).

I've improved the contact pressure on a number of battery packs by putting a glob of RTV under the contact. This works well for leaf-spring type contacts, but of course won't work for some other types.

You will want to avoid the FX-440. I built one five years ago, and having the good
test equipment (spectrum analyzer, signal generator, etc.) I can tell you that this
radio will interfere with many adjacent-channels on both sides. The internal L.O.
radiation was so bad that microphonics were evident, and the L.O. energy is strong
enough to cause some strange internal modulation effect in the PLL where the result
was a nice 25kHz comb on either side of the carrier, starting at only -6dB. Had to
completely shield the L.O. inductor to fix this.

The receiver front end is as wide as a barn door, and was subject to all manner of
intermod. Putting a multi-section helical filter in there helped that greatly, with
some loss of gain (of course). The squelch behavior is not all that pleasant either,
but I decided not to spend any more time on it.

Jan-Martin,

Is that a switcher or a really big secondary on the
transformer? Note that there was a two ot three-part article in QST
lat year or so for a hefty switching supply. You even get to wind
your oun transformers.

In NAZI Germany they had an "official" radio set to RX a single
channel. If you were to break the seal or modify it in any way
the penalty was DEATH. With all this emerging technology the
Klintonistas only want you to know how to push the buttons on
all the wonderful little black boxes and to dutifully pay all the
little ALGORE surcharges. They don't want you to have ANY
inkling on how the innards of these wonderful gadgets work or to be
able to build anythingof your own. QRP homebrewing is
becoming a big thing. Perhaps soon we will have to "register" our
experiments with the FCC and obtain type acceptance on
everything that xmits. An INGNORAMUS is a socialist/democrat's best
customer

Hi,

I have four pcs EIMAC 8252/4PR60C for sale. The valves are NOS and in original boxes. 8252 is the same as 715C and 5D21, but an upgraded version. Heater 25.5V 2.35A Pa 60W Va max 20KV Ia max 18A (pulse operation)
This valve is usually very expensive, but I'll sell it for US$ 100.-/each

Regards,

Hi,

I got a lot of these - about 75 - 80 I think. They have a B7G socket
and is about the same size as a 6AQ5 valve. All metal. Yellow colour.
The label says:
IF AMPLIFIER AM-427 A/U
FISHER RADIO CORPORATION
U.S.

They are new (or rather unused) and in original boxes. I really don't
need them myself, but maybe there is anyone out there who do?
E-mail me if interested.

Regards,

Arnold Goksyr

>I' need some information about the vacuum tube Eimac 8930,
>plate voltage , grid bias voltage ... schematics ..all that you know can
>help me so please write me to
>ipas.m@netclic.fr
>
This is easy. As the one responder has said, download the catalog. However, it is even easier than that. The 8930 is identical electrically in every way to the 4CX250R. The ONLY differance is the larger plate radiator diameter that allows more airflow with less backpressure. The 8930 is rated as a 350 watt dissapation tube.

Even over there in france you can find the specs for the 4CX250R. Check out the R.S.G.B. handbook.

If you use PC boards, there's nothing special you need to do -- just
solder the cap down one end at a time, perhaps holding it in place with
a toothpick. Otherwise, if you're not mounting them flat on a board,
the thing to remember is that their ability to withstand force applied
to their terminals is absolutely ZERO. Once you solder a chip cap into
a circuit using dead-bug construction, you've got to be careful not to
bend the leads attached to it at all.

Use a clean, hot iron with a small tip when hand-soldering these
puppies.

In "UKW Berichte" 2/96 (maybe also in the 2/96 English issue
"VHF-Communication") the calculations for a 1700 MHz coupled line bandpass
filter are described in detail. The author uses CalTech's cheap microwave
CAD software PUFF for calculation and simulation.

I'm not quite sure but the shareware filter synthesis program FAYSIN
(http://members.aol.com/faisyn/faisyn.htm) could also be used to calculate
line coupled bandpass filters. The programm's ouput is in PSPICE, TOUCHSTONE
and
MMICAD format.

Hi,

anyone who has build DG4RBF HF-Synthesizer 5...1450 MHz published in
UKW-Berichte 3/96 ??

I have build this, but i'm experiencing trouble with the micro-controller
section. At the startup procedure there appears to be going something wrong
as the controller does'nt write data to the LCD-display. I can start it up
by making pin28 of the 80C535 low. But then i have to program at each
start-up all of the stored data in the S-RAM chip which contains information
about power-levels from across the band.

My troll alarm is dangerously close to going off (Allied? Knight? Where
have you been?), but for what it's worth, I spend my parts dollars at:

- local (Toronto) suppliers like Active Surplus and Sayal
- Digi-Key for much of the rest
- Newark for first-order exotica (e.g. Analog Devices)
- Downeast Microwave and Mainline for RF stuff
- specialist suppliers like Mini-Circuits
- scrounge the rest wherever I can get it; try to score
samples of really weird stuff

Sure, there are minimum orders. That's how the business works
these days. Like others have mentioned, save up until you
have a minimum order ready to go, and be prepared to stock up
on essentials (there is little point in buying .1 uF capacitors
in quantities of less than 100). When looking to pad an order
I also look for interesting things that I might not otherwise
buy on a "what the heck!" basis. Some of them have proven useful.

Hi,

Can someone direct me to a construction resource for the construction of
a Tx/Rx pair (AM or FM) with crystal frequency control. OR..
can someone outline a block overview of a suitable Tx. I have a basic
understanding of Superhet AM Rx, and I have an understanding of VCO/PLL
FM detection/modulation, but the Tx component is my weak part. I have
access to Harry's (sm0v-you know who I mean) web page, but not being
sure which building blocks to use or modify, makes it a little hard to
proceed.

What am I trying to do? Build a Tx/Rx pair which will have a data
in/data out pin on the Tx/Rx respectively, which I can use for R/C and
data experiments. I envisage something in the order of 300-500 mW, and
the frequencies would be in the 27-40 MHz areas (Both Rx and Tx set by
crystal)

I would appreciate any assistance or guidance people can offer on this.
Thanks,

For sliding surfaces, dry-lube is good (a wax stick like a candle).

There is also a conductive grease in existence for this type of thing.

I bought some chip capacitors in the bargain bin at the electronics store..Im wondering how an amateur homebrewer could use them..they are good RF Values ie 150 pf 330 pf and rated at 50 volts BUT they are very small of course! Any recommendations? I might think of trying my 25 watt soldering iron with a delicate approach. Im thinking of using these little guys in a rcvr front end filter project with small torroids to make a small ..compact unit...73 Earl VE3AB

1212. Marconi EHT half bridge rectifier HTZ 24B

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-14 00:00:00 UTC
From: Frank Dinger <gm0csz.kn6wh@invertain.freeserve.co.uk>
Message-ID: <887o9q$6r3$1@newsg4.svr.pol.co.uk>
Source record: 63317

Recently I purchased from a surplus dealer 4 pcs Marconi - Lincoln , EHT rectifier ,model HTZ 24B

It is a half bridge (hence 2 units form a full bridge rectifier)
When increasing the forward bias voltage a current commences to flow when voltage is 12.4 V or 6.2V for half the unit . This suggests that inside the moulded unit are 2*(8 or 9) silicon diodes ,meaning that if the PIV for each diode would be 1000V ,the PIV for 1 rectifier leg is 8000 - 9000 V
The model happily survives a constant current of 500 mA - DC.

Marconi -Lincoln is now named Mitel Semiconductors

Can someone perhaps identify this rectifier and provide info on specified PIV and current rating.
It is my intention to use the units in the HV power supply unit for a HF RF power amp.

1217. Problem with noise blanker on TS-440S

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-14 00:00:00 UTC
From: Mike <ki5mp@DOTDOT.arrl.net>
Message-ID: <dpTp4.5501$39.239549@news.corecomm.net>
Source record: 63322
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

Greetings everyone.

I have an intermittent problem with the noise blanker on my Kenwood TS-440 and was wondering if anyone could shed some light on it for me.

I have a Chevy AstroVan with lots of ignition noise (comes in through the antenna). I'm running a Hustler antenna with three resonators - 80M, 40M, and 10M. I haven't spent a lot of time really getting to the root of the problem by eliminating the source because the noise blanker on the TS-440 has been working quite well - until recently that is. On 40 meters the noise blanker works sometimes and sometimes it doesn't. The s-meter reading on the noise level on 40M is an S-9. Depressing the noise blanker button sometime wipes the noise completely out and sometimes it doesn't do a darn thing - making weak stations completely unreadable. On 80M, the noise level is a S-7 and the noise blanker consistently does a good job of cutting it out. On 10M, the noise level is about a S-4 and the noise blanker also consistently does a good job of cutting it out. The intermittent problem only appears on 40M.

Does anyone have an idea what may be going on?

Thanks in advance for any help.

Source record: 63323
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.swap

Mike, the performance of the noise blanker depends greatly on the character of the noise. It works best on tall narrow spikes. Apparently on 40 meters the spikes are wider, or they are accompanied by other noises that the blanker can't handle.

It doesn't seem there is anything wrong with the noise blanker, just that your vehicle needs attention.

An idle opinion from an old timer who has been there, and who also runs a TS-440S mobile from time to time. But then I probably have a better designed car; I don't think too much of American made vehicles. That's another idle opinion, don't take it personally.

1220. An Idea for Direct conversion FM data....

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-14 00:00:00 UTC
From: Paul Breed <Paul@Rasdoc.com>
Message-ID: <38A8669A.AF4330AA@Rasdoc.com>
Source record: 63325

I'm working on building a truly tiny FM telemetry transceiver.
I want it to inter operate with standard APRS equipment, like the
Kenwood H7A.
So the system has to operate on 1200 Baud AFSK.

This system has two AFSK tones of 2200 Hz and 1200Hz.

I like the simplicity of a direct conversion receiver a whole lot.
If I set the LO = to the center frequency, then as the FM deviation
occurs
the frequency will be reflected around zero.
If I then slope detect the result it will appear that my input signal
has been full wave rectified.

So my 2200Hz tone will appear at 4400 and my 1200 at 2400.

In addition I can induce a small 50Hz deviation in my LO that I can
synchronously peak demodulate to do AFC on the LO.

I believe that I can make all of this run in a small uP or DSP.

Will this work?

Any comments?

Paul (Kl7JG)

I've found that applying flux to the surfaces makes mounting
SMT components much easier. The flux in the solder just doesn't
help much.

I need some info on two vacuum fluorescent driver chips. I have searched the web and have put a message on sci.electronics.components but have had no replies. So I am turning to the ham radio community where I have found help in the past.

The first driver chip is numbered 10938P-50 and also 10940-16. The second driver chip is numbered 10939P-50 and also 10939-11. I think the logo on the chips is Rockwell.

The drivers are on a board that I would like to use in a project. It contains a 1 line x 20 character (5 x 7 dots) Vacuum Fluorescent Display, the driver chips, and circuits to create the required voltages.

Can anyone supply info on these two driver chips?

Yes it is. A long time ago I built an image reject (IOW, SSB) mixer with an IF of 4 MHz and an RF frequency of 1.3 GHz. The LO was 652 MHz and the mixers used anti-parallel diodes as described in an old Ham Radio Mag article. The 2nd harmonic mixing did not interfere with the image reject operation at all. In those days, you couldn't get a prescaler that worked at 1.3 GHz for the PLL.

You ought to look at direct conversion FSK pager receiver designs,
like the ones they use in watch pagers. Two mixers in quadrature, LO
at the midpoint of mark and space frequencies, and a D-flip flop
is all you need.

Source record: 63333

As Rick says, a paging receiver is a simple architecture. I think Phillips makes some
nice direct-conversion ICs. You can also use the RX LO for your TX signal.
I think the PCB layout is more critical when doing a direct conversion receiver, so
you still may consider a dual-conversion.
If you really need AFSK TX and RX, then the design is a bit more complex than just FSK of the RF.
Either approach can be done with a simple CPU, although the use of a DSP would
allow much more room for increasing performance by improving algorithms.
If its a one-off project, I'd use a Phillips dual conversion integrated RX IC with a Exar AFSK modem chip, and skip the CPU.
Good luck,
John Sonnenberg

Source record: 63334

I've had good luck using perf board... Get the 1/10 inch centers with
copper donuts around each hole.

I find them at Radio Shack for a reasonable price.

If you position the surface mount resistor, or capacitor carefully, you
can solder it to seperate donut pads.

This is very convenient in that I can then add another surface mount part
from that same pad to another one to build up the circuit.

Or, insert a through hole IC from the non-copper side, and use small gauge
bus wire to connect the pins of the IC to the surface mount part next to it.

The net effect is, an easy semi "PCBOARD" prototype with the bus wire
serving as trace connections between the surface mount parts.

All in all, I find it just about as easy as a through hole prototype, and
a heck of a lot smaller finished product !!!

True, I do have to spend some time working out an approximate parts
placement, before assembly, but it is fast and allows using the small
surface mount parts even in a one off breadboard.

This is a packet data system, there HAS to be a CPU, so I thought I'd
make it
do as much as possible.

Also I was thinking using a single VCXO as both TX and LO source, so
the 50hz
shift to do AFC would be easy.

Paul

1234. VFO Stabilizer/Frequency Counter Boards

I built a small "static" tube-tester which just measures the difference in plate current for a 1Volt change in grid bias. That's easy, I just change the pot in the control leg for a 1V change in output from an LM337.

To get a little more complicated, however, I was wondering if one could "modulate" an LM337 in its "adjustable" mode by lifting the control leg from ground and inserting a 1V RMS sine wave. I have done this to make an adjustable 0-30V negative supply simply by inserting a positive reference in the control loop. (As you know, the lower limit of the LM337 is -1.25 unless you insert +1.25).

How angry is the LM337 goint to be if it is modulated in this fashion? I was thinking of only a 1kHz sine wave.

Well, it's on to the breadboard.

This kind of thing works fine and is the principle behind
popular designs for Gunn diode modulators.

Why not try it and see? Personally, I'd rather see "I tried
it and this is what happened..." than "Will this work?"

Sometimes you can get samples if you pretend to be experimenting.
Try Hosfelt Electronics....they have some at 455 Kc 6KC at about $.30 each

COMMUNIQUE SPECIAL D'INFORMATION de la C.F.R.R.

du 5 f�vrier 2000 N° 2000-02

Jugement du Conseil d'Etat. Un fait sans pr�c�dent dans les annales du radioamateurisme fran�ais.
S�ance du 5 janvier 2000 - Lecture du 26 janvier 2000 - Notification du 3 f�vrier 2000
Les requ�rants ont re�u le 4 f�vrier 2000 la d�cision du Conseil d'Etat concernant la r�glementation amateur.

Extrait des conclusions du Conseil d'Etat :

« ..qu'ainsi les dispositions des articles 2, 3, 4 et 13 de la d�cision homologu�e par l'arr�t« attaqu« ont »t« prise par une autorit« incomp»tente ; que ces dispositions »tant indivisibles des autres articles de la d»cision 97-453 du 17 d»cembre 1997 de l'autorit« de r»gulation des t»l»communications, les requ»rants sont fond»s « demander l'annulation de l'arr»t« du 14 mai 1998 du secr»taire d'Etat « l'industrie en tant qu'il homologue cette d»cision. »

DECIDE

Article 1er: : L'arr»t« du 14 mai 1998 du secr»taire d'Etat « l'industrie est annul« en tant qu'il homologue la d»cision 97-453 du 17 d»cembre 1997 de l'autorit« de r»gulation des t»l»communications fixant les conditions d'utilisation des installations de radioamateurs et de d»livrance des certificats et des indicatifs

radioamateurs.

L'article 2 : (�num�re les noms et qualit�s des requ�rants.)

Cons�quemment,
"La R�publique mande et ordonne au ministre de l'�conomie des finances et de l'industrie en ce qui le
concerne et � tous huissiers � ce requis en ce qui concerne les voies de droit commun contre les parties
priv�es de pourvoir � l'ex�cution de la pr�sente d�cision."

La CFRR ajoute que pour toute information relative aux cons�quences de droit de la d�cision d'annulation, les
radioamateurs peuvent s'enqu�rir aupr�s de l'administration de tutelle ou de la seule des trois f�d�rations de la
concertation nationale ayant donn� quitus � l'ART.

Message-ID: <38a9d61d.23976609@news.earthlink.net>
Source record: 63215

Does anyone know where clear polystyrene rods, tubes, or sheets can be
purchased? McMaster Carr used to carry it, for a price, but currently
only lists white high-impact polystyrene. I want low-loss material,
but they list their product as a "poor electrical insulator"
Thanks, Jim

You could try finding a dead Dentron MLA-2500 amplifier and try using the URL below which outline a conversion job on the above amplifier to use a 4CX400 which is similar to the 4CX800.

How about using a 572B? You can get the plans on how to build an amplifier
using this tube from:

http://www.svetlana.com/docs/TechBulletins/technoteNO.34.html

Instead of holding it down with a toothpick, stick it on a piece of
transparent tape, this way you can't loose it.
Don't wory about burning the tape with the iron, the chip cap will stay
on the tape even if you burn close to it.

Before you buy.

1254. murata ceramic filters: where to buy?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-15 00:00:00 UTC
From: ax9909@aol.com
Message-ID: <20000214200548.26295.00003317@ng-cn1.aol.com>
Source record: 63336

looking for a source of murata ceramic if filters. have not been having any luck finding a vendor who can supply in small lots, 1,2 or 3 at a time. i have a need for three or four different types [band widths]. these filters are at 455khz and come in many different pass-band widths and numbers of internal elements. i am looking for 6, 9 and 15 element units. the band widths i would be interested in are as follows: -6db -60db
4 kc..... to .....10 kc
6 kc..... to.....15 kc all filters must be 1500 to
2000 ohm
12 kc.....to.....22 kc impedence, input and output.
15 kc.....to.....25 kc

if anyone has things like these or can point me in the right direction to find a vendor, your help will be greatly appreciated.....thanks to all....."george"

1255. Non inductive resistors/sources

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-15 00:00:00 UTC
From: wb <willyacht@yahoo.com>
Message-ID: <vb3q4.26020$3b6.114245@ozemail.com.au>
Source record: 63337

I am looking for some non inductive resistors of about 100 to 150 watts in 12.5 , 200 and 450 ohm. Can anyone suggest some sources? Dale makes some resistors that are claimed to be non inductive, or close to it, would these be suitable for a grid termination for a tetrode amp?

will

1256. Re: Looking For a Home Built Big DC Power Supply.

Jan-Martin,

Give the article a look. the directions are really quite
explicit and the secondaries are wound with copper sheet. If I were
in the market for a power suply project, I would try it. Fortunatly,
a Drake TR-7 and PS-7 (25 amps at 13.8 volts) came my way and if I
need a LOT of DC, I can adapt the PS-7.

Message-ID: <88aotl$da2$1@bob.news.rcn.net>
Source record: 63340

I have a car battery that no longer has a battery, and thought it would do good as a emergency power supply. What I would like to do is use my Astron power supply to keep the battery charged. Does anyone have some ideas or schematics for a protection circuit?

Thanks,
Chris Kelling

Better yet, checkout Eagle (from CadSoft) Light at
http://www.cadsoftusa.com/freeware.htm

Freeware
The EAGLE 3.5 Light Edition can be used for free!
Limitations
The following limitations apply to the EAGLE Light Edition in general:
The useable board area is limited to 100 x 80 mm (4 x 3.2 inches).
Only two signal layers can be used (Top and Bottom).
The schematic editor can only create one sheet.
Apart from these three limitiations the EAGLE Light Edition can do
anything the Professional Edition can do. You can even load, view
and print drawings that exceed these limits!
The Freeware version of EAGLE Light adds these limitations:
Support is only available via email or through our forum (no fax
or phone support).
Use is limited to non-profit applications or evaluation purposes.
What does "non-profit" mean?
The definition of non-profit is fairly simple and straightforward:
If you earn money by using the Freeware version of EAGLE Light,
you have to register it.
This allows anybody who wishes to use EAGLE Light for their
private hobby projects to do so. Also students can use this version
for any educational projects. It is even ok to use this version in a
commercial environment, as long as you just want to evaluate the
program. As soon as you start using it for commercial projects, you
will have to register it.

I am NOT affiliated with CadSoft in any way beyond being a
satisfied customer for their professional version ...

However, the pagers use a rather large modulation index to create a
null at the carrier frequency, which maps to DC in the conversion to
baseband ... that way they can AC couple and get around the DC
offset problems caused by carrier self-mixing to DC which can be
a major problem.

> I have a car battery that no longer has a battery

What ?

You can buy special battery chargers. The important thing is to stop
charging when fully charged so you need a voltage limited supply. You also
need to limit the charging current to avoid self destruction. In addition,
you need to prevent the battery reverse charging the supply when the power
is off. A strategically placed diode will do this but will drop up to 0.7V
or so. There was a design in the ARRL handbook. You could also use a relay
driven from the supplies supply.

Can your Astron provide around 15-16V ? Does it have current foldback ?

Your Astron can not overcharge the battery.
(It does not have high enough voltage output.)
So the battery will never be full charged.
DO add a fuse/Circuit breaker AT THE BATTERY terminals.
(So you don't fuse the screwdriver/wrench etc...)

1263. a TNC made with PIC's???

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-16 00:00:00 UTC
From: tj@johnston.net
Message-ID: <38aa0dc6.15578277@news.mindspring.com>
Source record: 63218
Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,alt.hamradio.packet

Is anyone or any group currently working on a fully functional TNC made with PIC's? It seems these are very popular chips now.. and quite versatile. I would love to build my own TNC... in my own case... using these new chips. I am looking to do this for APRS and would love to build one with multiple rs-232 inputs for GPS, RDF and such...

Unfortunately I am not up to speed on PIC's ... yet... and would hate to re-invent the wheel.. if someone else is doing this already.

Tj Johnston, N4UYQ

1264. Re: VFD driver chips

Wow, this brings back some really old memories! These chips were indeed manufactured by Rockwell. They integrated a display controller and high voltage display drivers, and were manufactured using a unique high voltage PMOS process proprietary to Rockwell. Both parallel and serial interfaces were included. They were very neat chips in their day, as they typically replaced a microprocessor and a handful of high voltage display drivers.

The early production years of the Hewlett-Packard 5890A gas chromatograph used these chips to drive the front panel display. I designed the display board in that instrument in the early 80s, and although I am a terrible packrat, I just searched the old files in my basement and I don't appear to have retained copies of those Rockwell data sheets.

In order to use the chips you'll need their command set which is specified in the Rockwell data sheets. There is a special initialization sequence required, and various commands to take advantage of different display features, e.g. brightness, blinking, cursors, special characters, etc. Regrettably, I don't have a copy of the code I wrote to do that, either!

If you obtain a copy of the data sheets from Rockwell or somewhere else and have questions, feel free to contact me and I'll try to help. Good luck!

73,

John NU3E

Source record: 63220

To the person who wanted to know the consensus of this discussion:
(I'm sorry I lost the thread due to a computer malfunction...)
Many and different substances were suggested for use as a lubricant for roller inductors.
They were: (I hope I have remembered them all)

WD-40
Tuner cleaner/lube spray
conductive grease
silicone grease
teflon spray
ear wax !

If I've left anything out, please feel free to fill in.

I was trying to be funny when I said "Aint tellin'", but the truth is, I haven't tried anything yet to lube the roller inductor. I'm leaning toward the tuner cleaner/lube spray. I'll post how that works after I get the inductor motor drive working.
So, there are your choices so far!

Ordinary vaseline if the inductor does not get too hot from skin effect.
Replace every 6 months.

The vaseline is a hydrocarbon and cleans off surface films and debris. It
allows a true metal-to-metal contact, and provides a barrier to prevent
contamination.

My measurements show the contact resistance may decrease by a factor of
ten and becomes much more stable.

Comparing the results across multiple samples of the same kind of
connection shows the contact resistance becomes much more uniform from
unit to unit.

This works on any kind of electrical connection that stays cool. Nicad
and alcaline batteries, ram chips, high-current connectors, pcb gold
fingers, you name it.

It works. Just have to replace it after six months, which you need to do
with any contact cleaner.

Best Regards,

Michael R. Monett

Dear om
if you can help me I`ll be happy :)

I have a Transceiver (Kenwood TS-140S)
But it is not work now

SYMPTOMS :

First time : good receive but audible alarm " UNLOCK "
with morse code time to time .

Now : - open display firs time (forexample 14.000.00)
- after opened display (like . . . . .)
- not receive also not any sound or hiss
- not transmit
- alarm " UNLOCK " with morse code repeatly .
- when I rotate Tuning knob display is open
like 14.230.00 but again . . . . . .after 1 second.

I measured 3.2V on back-up lithium battery .

Try the VHF UHF Manual by G. R. Jessop G6JP fourth edition.
it's ISBN 0 900612 92 4 printed in Great Britan, but can be found
stateside. The tube schematics are great, but assumes you have experience
building amps. It's not a "how to" book. I'm asking for help myself on
building an amp using a pair of 4CX 250's. My problems are with building
the HV supply. I'll be experimenting with transformers out of dead
microwave ovens. It might save some serious money on transformers. If you
come up with something else that better addresses construction please let me
know. Thanks! mark KC7LTV ssparky2@thegrid.net remove one "S" in my

Does anyone have experience using old microwave oven transformers for a HV supply? I'm collecting parts for an RF deck with a pair of 4CX250R tubes. I'm using the schematic from the 'VHF UHF Manual' by Jessop. The transformer I scrounged gives 3,000 volts after a full wave bridge and a 16 Mfd cap,which is too high. I'm shooting for 2,000 to 2,500 volts. The current seems to be there given what the oven draws from the 110v side. I'm going to scrounge some more transformers to see if they give a usable voltage. I'd really like to hear from someone who's had experience doing stuff like this. My Elmer became a silent key last fall, so I could use some help. Please post a reply to the group or E-mail me.

In general, when you need something like that, the factory isn't interested in talking to you. Call a distributor, like Allied or Newark and ask them for what you want. Maybe they can't help but they will talk to the factory, and probably get more action than you can. Or a representative of the company that made the equipment, although it's probably too old for that.

Message-ID: <38AB8684.6DA2B4C1@NO-SPAMtcainternet.com>
Source record: 63237

Greetings,

Here's yet another one of my dumb questions. (U guys have a great sense of humor! Tnx for putting up with me)

I'm thinking of building a small HF amp for CW and SSB with a couple of 4-65As that I have laying around. My questions are as follows since I cannot find a circuit diagram using these guys.

I understand that this is one tube that CANNOT be run with grids grounded so:

If I go cathode driven, how do I calculate the amount of drive required for full output?

If I go grid-driven, how do I calculate the correct amount of grid 'swamping'. (The transmitters I have currently run single 6146 finals at about 90 W input)

In either case, any other configuration tips that are particular to these tubes from anyone with experience with them would be most welcome as well. (like their favorite plate / grid voltages, etc)

Thanks a lot guys (and gals???)

NOTE: To reply directly to me, please remove NO-SPAM from my email address. Sorry for any inconvenience but due to the HORRENDOUS amount of SPAM received as a result of posting to these newsgroups, I find no other easy solution.

Source record: 63238

Well if you can't ground the grids I guess you can't drive the cathodes. So if it's grid driven, you will probably need only a Watt or two for full power. That should give you enough information to calculate the swamping network. You might as well drive them from the driver of the exciter rather than using the final and throwing away 50 Watts of RF.

You didn't indicate what mode you will use, and whether you want the amplifier to be linear or not. If not, you can run it class C. In AB though the drive power will be very small.

I can't help you much more except that you can duplicate the circuitry of the exciter's final amplifier and hit it pretty close. As to the proper tube potentials, consult a data sheet.

There is a pliobond rubberized glue used in the v.c.o. circuit that
is normally a light tan color. It darkens to a brown or chocolate
color and becomes conductive. You must dig this glue carefully away
from the circuit board with a small dental pick, or pointed object.
Do not use a knife. This should restore the rig to normal operation.

so:

Correct, but you can still run them cathode driven with the proper bias voltages applied to the grid and screen.

>If I go cathode driven, how do I calculate the amount of drive required
for
>full output?

Look at the Class B data if you have it. Typically this will be for audio operation and the tubes will be run in push-pull. At RF, this is not necessary and the tubes are usually run in parallel. The grid bias will be that specified for audio service. The screen will also need the specified voltage. Both the grid and screen are "grounded" for RF with multiple, low-inductance bypass capacitors but these tube elements have their normal operating voltage.

The drive voltage will be the same as the Class B peak-to-peak drive voltage. However, the plate current will also flow through the cathode. This means the approximate drive impedance is the drive voltage divided by the plate current. With a pair of 4-65, this will likely be higher than 50 ohms. Knowing the voltage and current, you can calculate the drive power and what sort of impedance matching network will be needed to match the driver to the cathodes.

If the grid, screen, and beam-forming electrodes have a very low RF impedance to ground, the cathode driven amplifier will probably not need neutralization.

>If I go grid-driven, how do I calculate the correct amount of grid
>'swamping'. (The transmitters I have currently run single 6146 finals at
>about 90 W input)

A similar procedure is needed. Look at data for Class AB1, AB2, or B operation. The peak-to-peak drive voltage will be specified (and for AB2 or B operation, the grid current will also be specified). The specified grid bias and screen bias will still be needed. Your driver likely has

more than enough drive voltage (I don't have a 4-65 data sheet handy) to provide the P-P RF input voltage. If so, you can use a 50 ohm dummy load as the "swamping" resistor (AC coupled from the grid to ground) and back off on the drive for proper operation. To get more fancy, you can tap this resistance down to provide the proper drive yet absorb the driver's full power. If you do not have enough drive voltage, you can use a 1:4 impedance transformer on the input to double the drive voltage and quadruple the swamping resistance.

If the "swamping" resistor is low in value (generally less than 100 to 200 ohms), the amplifier should be stable without neutralization. Parasitic suppressors will still be needed, of course.

>In either case, any other configuration tips that are particular to these >tubes from anyone with experience with them would be most welcome as well. >(like their favorite plate / grid voltages, etc)

These little tubes really like a HIGH plate voltage, typically much higher than 811A's and other similar power tubes. Connection to the plate should be with a flexible lead to allow some thermal expansion. And a muffin fan blowing across the tubes is a very worthwhile addition to prolong tube life.

Many hams are confused by cathode driven amplifiers, and the term "grounded-grid" seems to be the real culprit here. Some tubes work fine with zero bias (like the 811A or 572B). Others like the 4-400 and 4-1000 work well with the screen connected to the grid to form a very high mu triode that requires no grid bias. But most tubes are like the 4-65 - the grid cannot be directly grounded. The 4CX250 family of tubes falls in this category. If hams used the term cathode-driven, I think much of the confusion would disappear. Any class of operation: A, AB1, AB2, B, or C can be obtained in cathode-driven or grid-driven operation.

1291. Where to get Pin Diodes?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-17 00:00:00 UTC
From: Rob <Pse@NoEmail.Com>
Message-ID: <gyUq4.26$hB1.1238@tor-nn1.netcom.ca>
Source record: 63246

Hello,

I am looking for replacement Pin Diodes for a Pin Diode RF switch but have had trouble finding any sources. The Pin Diodes part numbers are:

UNITRODE UM-4001D
UNITRODE UM-9415

Manufacturer??? KS-1001 (or is it K5-1001)

Does anyone have any ideas where I might be able to purchase these Pin Diodes??

Does anyone have the specs on these Pin diodes?? Are there substitute pin diodes made by other companies??

Any help would be appreciated.

1292. OT: audio cable

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-17 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <38AC1A52.C9684649@lafn.org>
Source record: 63247

Hi,
Can someone point me to a LOW COST supplier of single conductor
shielded audio cable I can use in homebrew projects.

Currently I am using RG174 coax but it is "way too stiff",
and is a litle to large at 0.110 inch diameter,
and 11 cents per foot is too costly. Flexibility is major concern.

Most suppliers have a very large min order, example Allied.

I am caniballizing VCRs and TV sets, but yield is very small.
Also, I have used the cable from walkman ear buds,
but this is TINY fragile shielded cable. Need larger diameter than that
to insure can prep cable without SMT techniques.

Thanks for hints.

Rob,

You might try RF Parts in San Marcos, CA. <www.rfparts.com> I bought several UM9415's from them a while back. They use to have specs at the back of their catalog. They have $25 minimum order but it doesn't take many high power pin diodes to make that.

1294. How easy is it to homebrew DTMF decoder?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-17 00:00:00 UTC
From: niebur@russell.mb.jhu.edu
Message-ID: <m2k8k3vlrl.fsf@russell.mb.jhu.edu>
Source record: 63249

Hi,

I am looking at VHF/UHF mobiles and, to my surprise, I discovered that only very few of them have DTMF paging (one notable exception being the Kenwood 261 but this seems otherwise to be a so-so rig, if one believes the QST test). So, here is my question: how difficult is it to homebrew a DTMF decoder, ie a little gizmo that switches on a connection only if it sees a certain pre-defined sequence of DTMF tones? Given the ubiquity of DTMF in the phone world and the need to control all kinds of things by DTMF tones, I would imagine there must be chips made just for that and it should be very easy to put together a simple circuit. Is that true? If yes, where can I find information abou that?

I have seen kits from Vectronics or similar that do DTMF decoding but they also do a whole lot of other things (like waiting for the phone to ring for a preselected number of times before switching on etc) which I don't need. Also, these kits are in the >$50.- range which seems like overkill for a very simple thing.

>that I have laying around. My questions are as follows since I cannot
find a
>circuit diagram using these guys.

O.K. here is a little trick I like to use for the family of Eimac
tubes with control grid problems.

Use a 4:1 impedance ratio (2:1) turns ratio balun between the exciter
and the control grid. Then connect 220 ohms of swamping from the grid
to ground. The grid will operate at zero d.c. bias. Use several large
zeners in series from cathode to ground (and a capacitor across them
to conduct r.f. to ground) to establish the bias voltage. Perhaps 50v
will be needed. I use several 50watt zeners in series. Run the screen
at recommended voltage (300 or there abouts) and run the plate on the
high side of specs.

Are your 4-65s any good. If they are old WW2 surplus they may be
so gassey that they are worthless.

Hi Jeff OM,
I can't help you with the meter, but is it the grid meter?
If so and the old one was zapped, highly likely it was due to a VHF parasitic taking off, and wiping out one or more 3-500Z's, causing a plate current surge which then takes out a lot of the grid metering ckt components, including sometimes the meter. Before firing up with that new meter, see Richard Measures' web page if you are not already aware of vhf parasitic problems he has investigated in lots of commercial and kit amps, including the Heath SB-220.

1300. Re: HV supply from oven transformer

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-17 00:00:00 UTC
From: AMDX <AMDX@worldnet.att.net>
Message-ID: <Ex%q4.408$rv3.23200@bgtnsc04-news.ops.worldnet.att.net>
Source record: 63255

Hi Mark,
Get a heavy duty 25V transformer, wire it with the opposite phase
(bucking)
in series with the primary of your oven transformer. Drive the primary of
your
bucking transformer with 120V. This will subtract 25v from the line voltage
to your
oven transformer and lower the output to 2375V. You can pick the bucking
transformer that works for you, or you could use a tapped transformer. You
might
even get real fancy and drive the primary of the bucking transformer with a
variac
and have more control of the output.
The secondary of your bucking transformer needs to handle the primary
current of your oven transformer.
Jan/Feb 1998 QEX magazine had an article about using oven transformers
for a HV supply, probably worth trying to get.
Also apparently oven transformers have magnetic shunts that need to be
removed for proper operation as a HV supply for an amp. If left intact it
will
cause poor regulation, according to the QEX article.
Let me know if I didn't explain well.

Small Aerospace firm always collecting resumes and future
employment contacts. Titles are irrelevant to us.
In keeping with the history of Aviation, we accept resumes
from everyone: Bicycle mechanics, hobbyists, HAM radio operators,
kit plane builders, rocket enthusiasts, as well as professional
engineers and scientists (undergraduate through graduate).

OPENINGS:

Aerospace Engineering, Electrical/Electronic, Mechanical:

Spacecraft / Rockets-- Design & Project Management, Systems Engineer,
Structures, Payload, Attitude Control, Telemetry, Flight Computer,
Tracking, Power, Thermal, all relevant subsystems from design through
flight following.

Other: Materials Engineering, Chemistry, Physics, Planetary Science,
and other related fields.

Aviation & Technical:

Airframe & Powerplant Technicians, Automotive Technicians, Electrical
Technicians, Machinists, Draftsman, CAD/CAM and other skilled labor
capable of enhancing our projects.

Hobbyists/Other:

Depending upon your skills, we also love working with people like HAMs,
skydivers, ultra-light pilots, kit builders, rocket & balloon
enthusiasts, and remote control fans. Often, these people provide a
valuable, experienced, and unique consulting & skills base in excess of
a standard engineer. Some even have educational and career
qualifications in excess of what we need. So, don't be shy.

COMPENSATION:

Arrangements run from 10% over your maximum job offers with full
employee package (for the super-duper engineers and grad students).

Other options include contractual work and partial ownership on a per
project basis. For example, when our engineers say "Hey! We should work
on something in that area."... we tend to recruit a CEO, CTO, and
project team and place that under a subsidiary relationship.

APPLICATIONS:

Email your resumes to: space_physics@yahoo.com

Thanks in advance for submitting to our HR database. We will not be replying to most applicants. Please indicate the length of time that you would be interested in tenure, geographic preferences, desired compensation range, and list your skills or experience by keyword.

Dear om
if you can help me I`ll be happy :)

I have a Transceiver (Kenwood TS-140S)
But it is not work now

SYMPTOMS :

First time : good receive but audible alarm " UNLOCK "
with morse code time to time .

Now : - open display firs time (forexample 14.000.00)
- after opened display (like . . . . .)
- not receive also not any sound or hiss
- not transmit
- alarm " UNLOCK " with morse code repeatly .
- when I rotate Tuning knob display is open
like 14.230.00 but again . . . . . .after 1 second.

I measured 3.2V on back-up lithium battery .

Source record: 63263

Lonnie, take a page from the Kenwood TL-922 mod info. It is therein suggested to rewire the filaments with 20 AWG wire. It has a high enough resistance to reduce the voltage to where you want it and it won't burn out with the current. It will get warm, so route it intelligently.

In the case of the Henry amplifier, the length of the path may be different so you might want to try different gauges.

The Richards transformation has to do with positive real functions in network synthesis.

Reference "Modern Network Synthesis" by Van Valkenburg, Wiley 1960, p.173.

An article by Richards, "Resistor-transmission-line circuits" is in the Proc. I.R.E, 36, 217-220 (1948)

The Richards Transformation was used by Bott and Duffin in the synthesis of one-terminal RLC networks. See J. Applied Physics, 20, 816 (1949) and also the Van Valkenburg book. This book is available from on-line used book stores.

Can anyone help me
I need a copy of the instructions for the Siskin Multi-cat interface.
I have obtained a non working one which I have repaired but I need the dip switch settings and the details of the pin-outs to make the lead from interface to radio (Yaesu 767GX)
I would appreciate any help or suggestions of where I could obtain a copy
Many thanks

Hi Lonnie,

How about a 15V bucking transformer in series with the primary of your
filament transformer.
A bucking transformer is wired with it's secondary in series with the pri.
of your filament transformer, but with the phase reversed. This will then
subtract 15V from your 120V line voltage, and reduce your 5.6V to 4.9V.
In case it's not clear you also need to apply 120V to the pri.of your
bucking
transformer. And make sure the bucking transformer sec. can handle the
pri. current of the filament transformer.

Certainly, everything's relative.

Good mic, excellent audio and ALC circuit, reliable
> power (5-10-50 watts switchable). Tolerant of antenna problems and
> car voltages. It's a little fussy (i.e., un-intuitive) to program,
> but I've had mine in daily use for over a year and can't complain
> about anything. And, as you said, built-in DTMF (but decoder is
> optional).

My understanding is that DTMF encoder AND decoder is built-in. I
thought it was the CTCSS decoder that is optional.

What's a better mobile transceiver for a lower price?

I don't know of any. HOWEVER, my impression is that for relatively
little money more (and again, everything's relative :), there are
better rigs. The lowest price I have seen for the Kenwood 261 is
179.-. The ICOM 2100 can be had for 193.- at AES and, at least on
paper, it looks a lot nicer. For again a bit more (209.- @ AES), the
Yaesu 2600 looks like a much newer rig with many more options, more
sensitivity, less intermod, higher power etc. If you add $60.- for the
CTCSS decoder on the 261 (standard in both ICOM and Yaesu), the
Kenwood is actually the most expensive.

Of course, neither the Yaesu nor ICOM have DTMF decoding (not even
optional). And, admittedly, all my judgement is based on reading
reviews and specs, I have no first-hand experience at all. If anybody has
any additional information about these three rigs (ICOM 2100, Yaesu
2600 and Kenwood 261), perhaps even first-hand experience with more
than one of them, I would certainly love to hear about that. I am
about to order one Yaesu (which I think is the best of the three) for
one of my cars and one ICOM for the other (the Yaesu does not fit into
the dash of that car).

> Bob KU8C
==========
A sturdy diode will prevent the above problem . However if the Astron PSU is set at 13.8 V ,you will charge the batteries only to say 13.1 V since approx 0.7 V is lost across the diode. This can obviously be overcome by adjusting the Astron PSU to 14.4 - 14.5 V.

Depending on the battery or batteries being charged it might be useful to limit de charging current to a reasonably low level . This will extend the life of the battery/batteries (especially when sealed gel type batteries are involved) and is no problem in standby mode.

A simple way to limit the current is putting a 12 V car bulb between Astron and batteries. A 50 Watts bulb or 2 in parallel would do the trick . Suppose the battery has been drained to 11.5 V (this should be the lower limit) then charging through the bulbs will take place on the basis of just over 2 V drop. The bulb(s) also have a stabilising effect , when current increases the filament gets hotter ,its resistance increases ,which causes the current to decrease . The glowing intensity of the filament is a measure of charged state of the battery.

I run all radio equipment in the shack including desk lighting on deep cycle ,lead acid batteries (the type used in caravans ,motor homes etc) with an installed capacity of approx. 400 Ah , The current charger can only do 2 Amperes which ,considering my operating habits , at the moment is more than enough to keep the batteries healthy. Shortly also the PC will join via an inverter. The next step is a solar panel and perhaps a wind generator. Not because of necessity ,but out of interest in renewable energy.

In QEX ,Jul/Aug 1999 there is an interesting article by Al Williams - VE6AXW
,on a regulated 2400V power supply , on the basis of thyristor control in
the primary winding of the HV transformer. HV Voltage swing during SSB or
CW operation is only 3 volts ..... at 2400 V HV. @ 1 kW load
The same principle could be applied for low voltage control ,eg for filament
voltage . You could even keep AC for the filament and only rectifiy a sample
voltage for sensing/control purposes.

Good Luck , Frank gm0csz.kn6wh@ukrs.org

Howdy,

I have the IC-706 MK II G. It seems from the manual that the mic input is 600 ohms. Is this correct?

I want to use my Shure mic from the Kenwood TS-830S. (MC-50). It has High and Low (50 KOhms, and 500 Ohms) impedence. Now, my hope is that I can match, say, the 500 to the 600 with a transformer (I can wind it??). Or, is there something better I can do? The shure mic is flat, I think... would that be good on a MKIIG?

One of the reasons I wish to do this is that I have a boom mount so that I can have hands-free operation... I already created the conversion cable ... that works fine. Just the impedence mis-match causes the MC-50 to currently be way to weak for good operation.

Thanks!

The question is what is the "terminal voltage"?

Battery charging is *much* more complicated than some of the ideas "floated" here.

See: http://www.statpower.com/tech4-2.htm and

http://www.amplepower.com/primer/index.html

for starters.

Howdy Tomas....Based solely on my experience, I wouldn't think that your problem is due to mismatch...(assume you are using the 500 ohm setup of that MC-50 of course). Impedance is only part of the requirement, with level being the other....output level of a particular cartridge, the directional characteristics of the microphone assembly and to a lesser degree the response curve of the mic can affect its use with a different transmitter.....the response curve will really affect the sound of it when SSB (suppressed carrier) mode is used. If that was my project, I'd want to monitor myself (or preferably someone else you know) using the combination to see if the response is acceptable...if it is, merely increase the mic level to suit - if its still not enough you may have to consider another cartridge OR an added preamp with just enough gain to restore good RF power output response to the audio input. Best of Luck!

Nice idea on the 118 MHz rock. Only one problem...the 11M noise is loud and dirty around here - or so I'm told, haven't spent much time on 11M since getting my ticket - the whole idea was to get away from the crud that 11M had degraded into. I'd be a bit concerned that one of these guys might be in the neighborhood, splattering into my IF rig. Of course, then again, our local OO (5 blocks away) fires up his Henry 3K Classic on 10M and wipes out my 6M on Field Days now. Lord knows what would pop up on a 28 MHz IF!

With the response I've gotten so far, will probably break down and order one tomorrow - unless I see something REALLY good in a 2M all-mode on the swap groups.

Thanks,
Jimmy KC7BDP

You might be more successful in getting results if you included more details.

Since it's an obsolete part, it's been around for about thirty years, there must be some reason why you want it. To keep an older piece of equipment going is a better reason than because you want to build some old project. In either case, there are workarounds, but it is easier to redesign when starting from scratch than when trying to retrofit something.

The NE561 is an analog phase locked loop, with an additional analog multiplier. The RC multivibrator VCO feeds directly to the phase detector, and the whole thing is rated at 15MHz minimum, and 30MHz typical.

What you are using it for, and the frequency range, would tend to determine how you could create a workaround. If it's just a straight PLL, without the extra analog multiplier being used, then any PLL that covers the needed frequency range would provide equivalent function.The CMOS 4046 is the most obvious choice, the Exclusive OR phase detector gives about the same effect as an the analog multiplier phase detector in the 561. Frequency is limited to the low MHz range, though the 74HC4046 will give you higher frequency coverage.

Any of the Signetics analog PLL's will give you the same basic PLL. The variations were function, such as some having a break between the VCO and the phase detector, or the added analog multiplier, and frequency range. If the 565 is still around, it always did seem more available, it would work, as long as you are using it below 500KHz.

TThe point is that once you get a suitable PLL, the extra analog multiplier that the 561 contains is relative easy to come by. The fairly common NE602 is the same basic circuit as used in the 561's analog multiplier (and phase detector for that matter). There are all kinds of ways to get an analog multiplier. In some cases, one might even be able to use CMOS transmission gates, like the 4066, as a digital equivalent of an analog multiplier.

You can get schematics for astron power supplies from the factory. Also consider buying the whole circuit board from astron. You'll get a great supply for a reasonable price. I'd suggest getting a tranmsformer first, then matching the schematic to the capability of the transformer. Good luck! mark kc7ltv

Take the AC component from the speaker port (via a capacitor),
amplify/rectify it and trigger your light with the resulting DC. If the
AC (at the port) is zero, no final DC will be got.
You can filter the original AC before rectifying it to avoid high
frequency noise to be detected.

There is no significant difference between a 500 Ohm and a 600 Ohm impedance microphone. Just connect it and it should work.

Hello group, has anyone the compactron Adaptor, Hickok part # 1704 or an equivalent that they can part with reasonably ?

Please respond privately if available.

It would be nice to test compactrons for gM with one of the TV-7's here.

BTW, got the tip for this off of the following page.

If you run a TV-7, check it out.

http://www.geocities.com/SiliconValley/6992/tv7.htm

This method is not too reliable. You need a method of locating all
sites pointing to yours, right? So - do a search using altavista,
for sites with links to yours.

The syntax for the link search is all on the Altavista advanced help.

Basically you search for link:blah.com.au/jabba
or whatever your site is.

This way you will find all sites linking to yours (within the currency
errors of Altavista) and you can compile an email list while you're at
it. Then when you next move your site, you can just email those
webmasters and request the change direct.

You will find other very useful facilities on the advanced help of
most search engines. The other one I use often is to limit the domain
range to sites in .au or .com. This does mean you won't find
Australian sites hosted at a non AU domain.

rudder_NoCannedOffal@gulfcoast.net (M. J. Clark) writes:

>I'm afraid I don't see your point. Are you saying that current regulation IS
>needed in addition to voltage regulation?

At least some sealed lead acid batteries do require current limiting during the initial charge, particularly if your initial voltage limit is set to 14.5 V or so for fast charging. I've seen one battery data sheet that specifies a charge current maximum that's 25% of the battery capacity (i.e. 0.25 C rate - 2.5 A for a 10 Ah battery). I've seen another manufacturer specify 0.4 C maximum.

In both cases, they recommend charging at constant current until the voltage rises to a particular limit, then maintaining that constant voltage as the charge current tapers. The voltage limit is set to about 14.5 V for fastest recharge, but in that case you can't leave the battery connected to the charger forever. A voltage limit of 13.8 V recharges more slowly, but is safe for indefinite "float" charging.

A 3-stage charger may current limit at first, then provide constant voltage of 14.5 V or so until the current drops sufficiently, then drop back to a constant voltage of 13.65 V or so for float - this gives fastest safe charge and safe float charging in the same unit. I've built a charger for small SLA cells using a commercial charger chip, and this is exactly how it works (and it does have settable current limit!).

Then there's Sonnenschein, who specifies just using 13.8 V with no current limit. They claim their battery self-limits the current to a safe value. They also don't recommend using 14.5 V for faster charging - just 13.6 to 13.8 V period.

Dave

1349. Re: Car batteries; and the charging of

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-21 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <38B211AD.7787D75A@eznec.com>
Source record: 63157

Panasonic sealed lead-acid batteries are specified to charge at 14.5 - 14.9 volts for cycle use, 13.6 - 13.8 volts for standby use. They also specify a maximum charge current of 0.4 C (for example, 400 mA for a 1 Ah battery). Yuasa batteries have similar specs.

These are liquid, not gelled, electrolyte batteries, but amateurs seem to call all sealed lead-acid batteries "gel cells" regardless. Gates sealed lead-acid cells use a starved electrolyte system. They're specified as 14.6 - 15.0 volts for a six-cell ("12 volt") battery for cyclic use, and don't have a maximum charge current spec. I wouldn't be surprised if gelled-electrolyte batteries have different specs yet. If you want your battery to last, you should check the manufacturer's specs for your particular battery. A lot of them are available on the web.

1350. DC power supply schematics wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-21 00:00:00 UTC
From: Chris Ross <pragmatist@kc.rr.com>
Message-ID: <38B081EB.5054469D@kc.rr.com>
Source record: 63292

I am looking to build a couple of nice power supplys to run my radios on and also for a bench supply for my workshop. I am looking for the following in one. A 0-14 vdc selectable output at 1-25 or 30 amps selectable amperage. Both voltage and amperage meters would be nice too. Can anyone point me in a direction to find a schematic to something similar to this? I am sure that I could manage to build a basic 25 or 30 amp supply easily enough, but don't know how modify the design to get the selector pots and the meters working correctly.

Thanks for all the help

Chris

Do you REALLY need voltages down to ZERO???
I can see starting at say... 1.25 volts or so, but ZERO?

There are several options...

I'd use a LM317K and PNP Power transistors.
Meters are trivial.

> Thanks for all the help

E-Mail me for a schematic.

What Transformer (Voltage/current) have you?

14.5 volts is unsafe for any gel cell that I have come across. The usual maximum voltage is specified at around 14.1 to 14.2 volts (temperature dependent). I have seen several rather expensive gel cells destroyed by charging at 14.4 volts for extended periods.

One of my two 4D's gel's was made by Sonnenschein. I have had it a long time, and it has always been charged to 14.1 volts, then floated to 13.6 volts. The literature that came with specifically stated a maximum terminal voltage in the very low 14's.

In any event, for any reasonable amateur application using a reasonably sized suitable lead acid battery (preferably deep cycle) floated across a station power supply (with isolation diode), there is no need to current limit as was suggested early in the thread.

Source record: 63162

Hello,

I have two old military surplus radios marked "radio receiver and transmitter BC-659-J" There is a number below that that reads "781 CQC 23121 phila 44-01." They appear to be two channel units and use tubes. It looks like they mount on a vehicle or possibly another piece of equipment like maybe a battery pack since all the tubes are all 1xxx. I've had these for 15 years plus and never been able to find the answer. Anybody know what they are? Could you point me somewhere?

Thanks

Tom

>specify a maximum charge current of 0.4 C (for example, 400 mA for a 1
>Ah battery). Yuasa batteries have similar specs.

Roy, the thread originator was asking about car batteries, which at least implies that he was considering something with a capacity that would be reasonable for fixed station use. A 1Ah battery might be a tad small <g>.

It has been my experience that when lead acid battery manufacturers talk in terms of 0.XC, they are really refering to charger capacity, not to current limited charging.

>
>These are liquid, not gelled, electrolyte batteries, but amateurs seem
>to call all sealed lead-acid batteries "gel cells" regardless.

Well perhaps, but I have never run into that. Anyone who ever had to price (or pay for) large capacity gels will certainly know the difference.

>Gates sealed lead-acid cells use a starved electrolyte system. They're
>specified as 14.6 - 15.0 volts for a six-cell ("12 volt") battery for
>cyclic use, and don't have a maximum charge current spec. I wouldn't be
>surprised if gelled-electrolyte batteries have different specs yet.

They absolutely are different. Gel cells charged to 14.6 - 15.0 volts will almost certainly be damaged. The absolute maximum voltage for gels is normally spec'd at 14.1 to 14.2 volts.

>If you want your battery to last, you should check the manufacturer's specs
>for your particular battery. A lot of them are available on the web.

Right, whether flooded cell, starved electrolyte, gel, or other lead acid technology is used, it is imperative that the charging system be adjusted properly. Different battery technologies require different charging techniques and voltages.

I have just built a simple little 500milliwatt 20m QRP tx and am now looking to add a simple transistor switching break-in circuit to enable me to use it with a separate receive r. Can anyone point me in the direction of a simple circuit that might work to do this?

Lonnie OM,

See Richard Measures' web page. He has addressed many of the design shortomings (and there are several) in the Henry, Drake, Kenwood amps. High filament voltage is one of them. I have found him to be very helpful.
See: http://www.vcnet.com/measures/

1361. Weird stuff: tiny resonant antennas

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-22 00:00:00 UTC
From: Science Hobbyist <bbeaty@microscan.com>
Message-ID: <88uuscirk1@nnrp1.deja.com>
Source record: 63166
Cross-posted to: rec.radio.amateur.homebrew,sci.physics.electromag

Here's some weird ramblings I've posted on my site:

ENERGY-SUCKING ANTENNAS (electrically small resonators)
http://www.amasci.com/tesla/tesceive.html

MORE MUSINGS ABOUT ENERGY-SUCKING ANTENNAS
http://www.amasci.com/tesla/tescv2.html

Briefly: if an atom is 0.1 nanometer across, how can it
intercept light waves which have 500 nanometer wavelengths?
As an "antenna", an atom is far too small!

Answer: the atom resonates electrically, which creates a
strong synchronous AC field in its nearfield region. The local
e-field and b-field of the atom superposes with the fields of
the incoming EM waves, which causes the waves to bend towards
the atom. If we plot the Poynting vector field, we find that
the atom "sucks in" the energy like a miniature black hole.
As the waves march along, the phase of the atom's fields stay in
step, and the Poynting vector keeps pointing in towards the
atom. This works even though the atom is extremely small compared
to the wavelength, since the fields of the nearfield region *ARE*
the antenna.

The same thing occurs with conventional radio waves and
electrically small dipole antennas if a large AC voltage is
impressed upon the antenna. The same thing occurs with small
loop antennas if they are given a large current. Actively
resonating antennas draw in far more energy than passive
pickup coils. In theory, a tiny loop antenna can behave as if it
were electrically enormous, and can reach out and intercept
huge amounts of energy. At VLF frequencies, this effect
is significant. Nikola Tesla could have used this effect as part
of his "wireless power" scheme. It explains how even a tiny
antenna could intercept significant VLF wattage.

And you thought "crossed-field antennas" were weird! What about
the loopstick inside an AM receiver?

Source record: 63167

A lot of QRP rigs use this scheme:

From the tranmitter output transistor collector, put a small series capacitor (around 27 pF or so). At the other side of the capacitor, put two 1N914-type diodes to ground in parallel, one facing each way. (That is, ground the cathode of one diode and the anode of the other.) From this junction of the capacitor and two diodes, add a series inductor which resonates with the capacitor. (This is about 30 uH for a 27 pF capacitor.) The inductor value isn't very critical, and the inductor doesn't have to be good quality; a molded unit is good enough. The other end of the inductor goes to the receiver. You can omit the inductor if the signal to the receiver is strong enough without it. (The way to test is to disconnect the antenna. If the noise level drops, the receiver is getting enough signal, and more won't help.)

I first came across the capacitor-diode scheme in Hayward and DeMaw's _Solid State Design for the Radio Amateur_, and added the inductor to increase the signal to the receiver.

Thank you for your interest in our training Course! We offer the most extensive training course in "How to Collect Judicial Judgments" available!!! In fact, we created this industry.

If you are like many people, you are not even sure what a Judicial Judgment is and why processing Judicial Judgments can earn you very substantial income.
When one person or business files suit against another person or business and wins, then winner than has a Judicial Judgment. You are happy you won, but you will soon find out the shocking
fact: "Its now up to you to Collect on the Judgment". The court does not require the loser to
pay you. The court will not even help you. In fact, employees of the court are forbidden by law from
telling you how to collect the judgment. Basically, the winner has a piece of paper. You must trace the loser down, find their assets; their employment, bank accounts, real estate, stocks and
bonds, etc. The nations most recognized private investigator will teach how to do it all!

Very few people know how to find these assets or what to do when they are found. The result is that millions of Judgments are just sitting in files and being forgotten. This is entirely
non-
confrontational and requires no special licensing.

Right now in the United States there is between 200 and 300 billion dollars of uncollected Judicial Judgments. For every Judgment that is paid, 5 or more Judgments take its place.

The income potential is substantial in this profession. Using the techniques taught in this course, people are now working full-time making $96,000.00 to over $200,000.00 per year, Part-time
associates are earning between $24,000.00 and $100,000.00 per year. Most choose to
work out of their homes, other build sizable organizations.

Today, people trained in this business opportunity are processing over 500 million dollars in
Judicial Judgments.

So, if you've ever dreamed of the financial freedom that owning your own business can provide. Dreamed of an early retirement, this may be the opportunity for you. None of your days will be dull.
You will be mentally challenged. This business protects you from corporate downsizing. This business is your ticket to freedom from others telling you what to do. This business lets you

control
your destiny! Our training has made this happen for many others already, Make it happen for you!

If the above sounds interesting to you then its time for you to talk to a real live human being,
no cost or obligation on your part.

Please call us at 1-303-423-9190, between the hours of 1:00pm - 6:00pm Mountain Time
(our mornings are reserved for support of our associates), Monday -friday.
Thank you for your time and interest.

Bill:

So what limits the energy "sucked up" by the ferrite rod antenna in that AM radio? I don't think I ever heard of a loopstick melting right out of one of those cheap plastic radios.

Also, specifically which "theory" are you referring to when stating that a small loop antenna can be "electrically enormous"?

Ed

At last, someone has stated what i figured 10 years ago!

If the losses in a ferrite rod antenna are made very low,
the currents will become much higher, limited only by the
radiation resistance which is very low for around 1MHz.
The selectivity will also become sharper.

1371. Simple broadening of CW receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-23 00:00:00 UTC
From: n2cqr@erols.com
Message-ID: <38b3bae4.4966593@news.erols.com>
Source record: 63176

I was tinkering with my version of Doug DeMaw's Barebones Superhet Receiver (20 meters, single conversion superhet using mostly 40673 dual gate MOSFETs, 3 crystal ladder filter using 3.359 color burst rocks). I wanted to be able to listen to SSB signals but the crystal filter was too narrow. Not wanting to go to the trouble of building a proper 2-3 kc wide filter for the phone signals, I decided to come up with an arrangement to just "switch out" the crystal filter.

I used two switching diodes controlled from the front panel. When the switch is thrown the diodes are turned on and, in effect, a jumper wire goes from the output of the LC tuned circuit at the input of the filter to the input of the LC tuned circuit at the output of the filter. IF selectiivity is then limited to that provided by the two LC tuned circuits.

I found that with the insertion loss of the crystal filter thus eliminated, I was getting too much IF gain, so instead of just switching in the jumper wire, I now switch in a 10K pot that I can adjust to keep the gain roughly equal to that that I get with the filter switched in.

This is a very easy way of being able to use those very narrow CW receivers for casual phone band monitoring. This morning I fired up the receiver and was able to listen to some VKs involved in a very pleasant discussion of the southern aurora!

Somehow I have misplaced my Microphone for my Icom 735 while we moved from one boat to a another. I have a non Icom mike and wonder if it will work on my radio and how to hook it up. I have the 8 pin plug. The mike I have is marked GE Communications on the front, and on the back is 344A4528P55 Rev B, Assembled in Mexico.

It has 5 wires and I assumed Black is ground or common, so

Blk to red= open and then "0" with PTT
Blk to Grn= open and then 2 meg with PTT
Blk to wht= acts like cap is charging I stopped at 22 meg. PTT no effect.
Blk to Blue= 4.5mg, PTT no effect

Can I use this mike and how would I hook it up to the plug. Please give how I should look at the plug, front or back.

Thanks Norm

It's around 2.1 uH or the result of:

L(uH)= a**n**/(9a + 10b) where

a = external coil radius (inches)
b = coil length (inches)
n = number of turns.

This formula is valid for closewound coils and with b >= 0.8a.
Please, recalculate it for security.

1375. Problem with President HR2510 (long post)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-23 00:00:00 UTC
From: Mike <ki5mp@DOTDOT.arrl.net>
Message-ID: <B7Us4.255$Ag.7374@news.corecomm.net>
Source record: 63180
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Greetings,

I purchased a nice little HR2510 from an individual and it suffers from low power output. I have replaced both the driver and final transistors and aligned the transmitter section per the service manual. The maximum output power obtainable on CW and SSB is around 15W. The AM output power can be adjusted to its specified output of 10W and FM is also low at around 7W.

In the process of doing some circuit tracing, I noticed some minor differences between the actual main board and the service manual schematic. For example, the service manual block diagram depicts Q134 as a TX AMP, but on this main board there is no Q134 - there is a Q140 and associated biasing resistors in the immediate area instead, for which there is no such component listed on the block diagram or schematic. The board has mounting holes and silk-screening for Q134 and R167, but Q134 is bypassed with a capacitor where the base and emitter leads would normally go.

This may be a dumb question, but is there an "European" version of this radio? This radio was supposedly purchased in the Netherlands while on a business trip and brought back to the U.S. The silk-screening on the main board identifies it as a PB-111AE instead of the PB-111 designation indicated on the schematic. The schematic printed in the owner's manual has the same schematic as the service manual, for a PB-111 main board.

A little more history on this radio may be in order here. This radio was supposedly a 'new' radio but when it first arrived at my door and was tested, it suffered from apparent parasitic oscillations when operated in SSB mode. It operated perfectly on a dummy load, but when hooked up to a real antenna system and modulated in SSB mode, the power output would "latch" ON at full output (about 25W PEP) and not drop back with no modulation as it should. (I might mention that there is nothing wrong with the antenna system - I tried the radio on three different resonant systems with the same results.) I returned the radio back to the individual and he 'repaired' the radio by replacing the driver transistor (Q133). He first replaced the final transistor and this didn't solve the problem, but the driver replacement apparently did. I received the radio back and the parasitic oscillation problem did appear to be fixed, but then I noticed the power output was significantly lower than it was before and the SWR meter no longer worked. Follow up e-mails with the individual yielded no results to my satisfaction but I decided to keep the radio because it is in such good shape cosmetically.

So, I replaced the driver and final transistors again myself and aligned the PLL and transmitter sections per the service manual with no noticeable gain in performance. Digging deeper I noticed the aforementioned minor circuit

differences (and there may be more.) I have a sneaky suspicion that this (or the original) problem may be related somehow to the SWR detection and/or automatic power cut-back circuitry. As I mentioned, the SWR meter no longer works

Is there anyone out there that has a schematic for the PB-111AE main board and/or any suggestions?

Any input would be appreciated. I apologize for such a long post...

> impressed upon the antenna.

Is a large voltage/current necessary? Consider a high permitivity peizoceramic will suck electric flux in, and a high mu ferromagnet will suck magnetic flux in. A shorted multi-turn solenoid, having a greater reluctance than free space will suck in magnetic flux too?

This is part of the mystery of field-theory, wheather you prefer aether or virtual photons. If you place a relatively lower-resistance metal on a carbon sheet that has a voltage gradient, and plot the voltage on the sheet, you will notice a reduced voltage gradient around the low resistance metal object. How does the current know to bend towards the metal discontinuity?

Same with current flowing in bent metal. How does current know to bend smoothly rather than sharply? Electrodynamics has some answers. But the same gradient, or pit, occurs around lower permitivity and permiability materials. Regardless of the energy they contain.

I realy doubt it. I believe a highly charged small resonant circuit could cancel out a complementary field.

It seems you have the picture in mind of what powdered iron does around a magnet. I have heard stories about a steel chain around a superconducting magnet, that when energized, became so rigid it could be sat on, unsupported on end. I don't think that is true of space, at least at typical energies. I realy doubt passing more current in a solenoid will reduce its reluctance, or increase permiability.

I imagine that the resistance of the wire, and maybe the losses in
the core would be the biggest limiting factor. If the current in
the loop antenna determines the "effective area" of the antenna,
but also the effective area of the antenna determines the
energy received (and so determines the current) ...then it sounds
to me like feedback, and if so, then there'd be exponential
growth initially when the circuit is first assembled. If the Q
is low, the current would never get to the steep part of
the exponential growth, so wouldn't rise to unexpected high
levels. We might never see any sort of "meltdown", because the
slight heating of the wire nips the growth process in the bud.

That doesn't mean the current wouldn't grow disproportionally huge
if the Q was made much higher.

Also, this phenomenon would be expected to occur at lower
frequencies. If the frequency is high, the effective area would
never become really huge. If the nearfield is assumed to be about
1/3 wavelength wide, then at 500KHz a "superconductor loopstick"
would act like an absorber-disk 200 meters across. That sounds
large, but for a 10KW station at 10KM distance, the ideal
antenna could only grab about a quarter of a watt. Even so, it
would be pretty neat to run a solar-cell motor using a little
bitty antenna.

> Also, specifically which "theory" are you referring to when stating
that
> a small loop antenna can be "electrically enormous"?

The ones discussed in these two papers mentioned in the references:

C. F. Bohren, "How can a particle absorb more than the light incident
on it?", Am J Phys, 51 #4, pp323 Apr 1983

H. Paul and R. Fischer "Light Absorbtion by a dipole", SOV. PHYS. USP.,
26(10) Oct. 1983 pp 923-926

The above authors analyze the effect in terms of atoms and light waves, but the phenomenon is classical physics, so it works for any electrically short antenna connected to a high-Q resonator.

These guys below used the effect as part of a NASA project to study ELF radio. They added active feedback to a loop antenna in order to increase the received energy while allowing the system to remain broadband. If the point is to create a local field in synch with the incoming waves, then it doesn't matter how you do it. You can build a resonator and let the received energy build up a large field. Or you can drive the antenna with a op-amp in a feedback loop that nulls out the wire resistance.

J. F. Sutton and C. C. Spaniol, "An Active Antenna for ELF Magnetic Fields", PROCEEDINGS OF THE INTERNATIONAL TESLA SYMPOSIUM, 1990, International Tesla Society, 1990

I've yet to draw any pictures, but here's one way to convince yourself that this stuff is real. Plot the field lines of one cycle of an EM wave (basically some parallel lines), then superpose the field of a small dipole placed at the spot where the transverse field lines of the EM wave go to zero. The EM wave distorts the field of the dipole, so erase the dipole's field and re-draw it with the appropriate distortion. Now draw some flux lines perpendicular to the lines you've already drawn. These transverse lines show the Poynting-vector energy flow. It comes in from the side, following the EM wave as you'd expect. Then it plunges into the dipole from all sides. (The above papers contain proper diagrams.)

Apparantly ALL antennas do this (they "attract" the Poynting vector lines so the lines dive into the metal surface of the antenna elements.) That's how thin wires can intercept those big broad EM wavefronts. The weirder things only start happening when we make the wavelength enormous, then use a tiny resonator as an antenna rather than a long thin wire. Also, I think it pays to use voltage-mode antennas (dipoles with lots of volts on them) rather than loop antennas, because the loop antennas rely on high currents and consequent heat losses. Build a resonator with small C and large L, and hook it to a dipole. (As opposed to using large C and small L, and hooking it to a loop antenna.)

When I first started jabbering about this last September, somebody mentioned that a massive loop antenna made from copper pipe can pick up significant energy. There's a guy in Chicago who runs little motors using high-Q resonant antennas (makes for a good perpetual motion hoax!) But if he had an AM tower within a few thousand meters, then that's not so impressive.

What would be impressive is if a resonator could be persuaded to build up a high voltage rather than a high current. Maybe it would take the shape of a tesla coil secondary, but super-conductive. Even if it can intercept a fraction of a watt, a corona discharge at that wattage would be amazing.

Not such a good thing, if the resonant circuit Q is greater about 200
the bandwidth gets so small that it cuts off the sidebands, which, after
demodulation, attenuates the high freqencies of the base-band signal.

Regards
Rob

Nope, it's just the usual e-fields and b-fields that appear
around capacitors and coils. If the coil or capacitor is way
smaller than a wavelength, then you are able to create very strong
AC fields without having much radiation loss. The weird part is
that these fields can themselves act like an "invisible antenna."
They don't radiate, but they do interact with incoming waves if
the waves and the oscillating fields are in synch.

But after thinking about this for weeks, I see that it's not
so weird after all. Ever it was thus. Your normal half-
wave receiving dipole does exactly the same thing. It generates
a local field which, when superposed on the incoming waves, bends
them so that their energy "flows" into the extremely narrow
antenna wire.

We never think about it, but these relatively narrow wires always
have a relatively huge effective area. How can a LINE act as
a good absorber, when the waves look like a PLANE? The line
causes the planes to collapse inwards. If the same is true of
a "pointlike" antenna, and if small antennas can easily
absorb plane waves much larger than themselves, everyone gets
weirded out. But we should also get weirded out about the thinness
of conventional antenna wires.

I think this is the same effect. The EM waves can induce a current
in a loop antenna, but they can also align a bunch of electron
spins in a ferrite rod. In both cases there is energy stored
as fields around the antenna, and the enhanced fields cause a
greater energy flow to be diverted into the antenna from
surrounding space. I guess an LC resonator is like a "giant
iron atom" (or an iron atom is like a tuned loop antenna.)

However, a PZT or ferrite rod is broadband. The effect should be
much larger during resonance because the stored energy in
the resonator can build up to a high level and create a much
larger field. I think.

discontinuity?

This resonant-antenna idea would be equivalent to replacing your
metal object with two electrodes connected to a tiny battery.
It bends the fields at a much greater distance than a passive
object. Or better yet, make it passive but let it power
itself: connect a large-value capacitor to the electrodes. As
the drive voltage on the carbon sheet pumps current through
the capacitor, its voltage rises, but its incoming wattage does
not remain constant. The capacitor intercepts energy at a
greater rate when it is partially charged than when it is
totally discharged. By DRIVING those electrodes, our receiver
can absorb more energy. It's not a perfect analogy, but I think
it illustrates the basic idea behind a driven (oscillating) antenna.

> > The same thing occurs with small
> > loop antennas if they are given a large current. Actively
> > resonating antennas draw in far more energy than passive
> > pickup coils.
>
> That is news to me.

It's the weirdest part! Suppose I set up two big metal plates a
few feet apart, and connect a high-freq AC power supply to them.
Any small pair of "pickup plates" with a load resistor could
intercept some of this energy via capacitive coupling. We
could improve things by chosing the right load resistor to
draw maximum power from the pickup plates. However, what happens

if we connect a coil across the pickup plates and tune it
for resonance? A big oscillation builds up. The voltage across
the plates grows much higher, but the induced current going
through them does not drop in proportion, and this means that
the received power is higher. It resembles impedance matching,
but it's really something different. It involves the e-field and
b-field in the region around the plates rather than the impedance
of circuit components. Rather than "impedance match", it
more resembles an increase in the AREA of the pickup plates.

Yes it's just a "coupling" effect. But where EM waves are
concerned, whenever we "couple" to a larger region of space,
the effective area of the antenna becomes larger, and it
essentially sucks energy in from a greater distance around itself.

As a friend pointed out, AM radio really "sucks."

I like the concept of the jar of sodium gas which blocks sodium
light but passes everything else. Those atoms are way smaller
than the light waves, right? At most frequencies they act small,
and the gas is transparent. At the sodium line frequency, how
is it that they can block the light? Simple: each atom grows
a fuzzy black cloud around itself, and the cloud is made
of oscillating EM fields at the resonant frequency. The "cloud" is
in synch with the sodium light, so it only looks big and black to
the waves at that frequency. When you tune your light to the
right frequency, the little atoms seem to swell into big
black puffballs. So does the loopstick in a portable AM radio.
Or so this "resonant antenna" concept says.

reluctance,
> or increase permiability.

Hey, that's it! That's what's happening. It doesn't have anything
to do with the DC permiability of course. Because the
oscillating fields of the tuned circuit are locked in synch with
the incoming EM waves, they present a constant "back EMF" which
lets the antenna interact more strongly with the waves. It only
works at a particular frequency, but at that frequency, the
loop antenna would seem to attain a huge permiability, and it
would distort the fields across a much greater volume of space,
as if it had grown a big ferrite rod down its middle.

It's an OLD tube that has no CATHODE, I doubt you are using any of this
type.

And ALL tubes have directly heated filaments.

Grounding the grid isolates the cathode from the plate for RF purposes.

Small resonant antennas can be very effective. If you have a lossless small
antenna its receiving area is wavelength^2/4pi, no matter how small it is.
So at 1MHz even a tiny antenna has a capture area of about 700 square
metres.
BUT there's a catch - it has to be a lossless antenna and the impedance of
the
load (i.e. the input impedance of the receiver) has to be the complex
conjugate
of the antenna impedance. If the antenna impedance is (say) 10^-3 - j1000
there is a problem in matching that without introducing losses. There's
another
catch - the Q factor of my example is 10^6, which means that its
bandwidth
is only 1Hz for a 1MHz carrier frequency. That is useless for just about
any purpose.
Loopstick antennas as used in radios are effective for their purpose but
they
are very lossy. It doesn't matter because enough power is transmitted to
allow the programme to get through. With one transmitter serving 1 million

cheap receivers the economics of this system is right. For communications,

when there is 1 transmitter and 1 receiver, it is better to transmit less
power
and use a more efficient receive antenna.

1392. Problem with Uniden HR2510

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-24 00:00:00 UTC
From: Mike <ki5mp@DOTDOT.arrl.net>
Message-ID: <CF9t4.372$ak5.13590@news.corecomm.net>
Source record: 63104
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.cb,rec.radio.swap

Greetings,

I purchased a nice little HR2510 from an individual and it suffers from low power output. I have replaced both the driver and final transistors and aligned the transmitter section per the service manual. The maximum output power obtainable on CW and SSB is around 15W. The AM output power can be adjusted to its specified output of 10W and FM is also low at around 7W.

In the process of doing some circuit tracing, I noticed some minor differences between the actual main board and the service manual schematic. For example, the service manual block diagram depicts Q134 as a TX AMP, but on this main board there is no Q134 - there is a Q140 and associated biasing resistors in the immediate area instead, for which there is no such component listed on the block diagram or schematic. The board has mounting holes and silk-screening for Q134 and R167, but Q134 is bypassed with a capacitor where the base and emitter leads would normally go.

This may be a dumb question, but is there an "European" version of this radio? This radio was supposedly purchased in the Netherlands while on a business trip and brought back to the U.S. The silk-screening on the main board identifies it as a PB-111AE instead of the PB-111 designation indicated on the schematic. The schematic printed in the owner's manual has the same schematic as the service manual, for a PB-111 main board.

A little more history on this radio may be in order here. This radio was supposedly a 'new' radio but when it first arrived at my door and was tested, it suffered from apparent parasitic oscillations when operated in SSB mode. It operated perfectly on a dummy load, but when hooked up to a real antenna system and modulated in SSB mode, the power output would "latch" ON at full output (about 25W PEP) and not drop back with no modulation as it should. (I might mention that there is nothing wrong with the antenna system - I tried the radio on three different resonant systems with the same results.) I returned the radio back to the individual and he 'repaired' the radio by replacing the driver transistor (Q133). He first replaced the final transistor and this didn't solve the problem, but the driver replacement apparently did. I received the radio back and the parasitic oscillation problem did appear to be fixed, but then I noticed the power output was significantly lower than it was before and the SWR meter no longer worked. Follow up e-mails with the individual yielded no results to my satisfaction but I decided to keep the radio because it is in such good shape cosmetically.

So, I replaced the driver and final transistors again myself and aligned the PLL and transmitter sections per the service manual with no noticeable gain in performance. Digging deeper I noticed the aforementioned minor circuit

differences (and there may be more.) I have a sneaky suspicion that this (or the original) problem may be related somehow to the SWR detection and/or automatic power cut-back circuitry. As I mentioned, the SWR meter no longer works

Is there anyone out there that has a schematic for the PB-111AE main board and/or any suggestions?

Any input would be appreciated. I apologize for such a long post...

:-)

>Grounding the grid isolates the cathode from the plate for RF purposes.

But 50c/s(UK) 60c/s(US) isn't RF. And no cathode.
I Thought about the thermal inefficiency, but concluded that that was
why cathodes were invented. If you have ever experienced a
heater/cathode short, you will be familiar with the magnitude of hum
that is created.

A friend, EI9GQ suggested an answer which I think is correct. The
filament is always fed with a centre-tapped transformer, which feeds the
current in anti-phase and therefor the hum is self cancelling.

Sounds plausible to me when I recall the 'humdigers' we used to use on
audio amps. in my teens, but it's such a long time ago.

>-rob

It is difficult to calculate the exact inductance of an
air cored inductor. Using the ARRL handbook formula:

d^2 n^2 / 18d + 40len gives a result of about 0.26 microHenries.

d = coil diameter in inches
n = number of turns
len = coil length in inches.

The W6GGV and G4FGQ programs both give a result of about
0.3 microHenries.

Barry OM,
There is no AC hum on the signal for two reasons:
1). The large amount of plate current drawn (large fractions of an ampere), tends to swamp out the tiny variations due to the filament temperature following the AC filament voltage excursions. In addition, large filaments have sufficient thermal mass to greatly attenuate changes in the space charge around the filament due to AC on the filament.
2). The cathode current DC return is via a center tapped filament transformer winding, which, as a first-order, cancels the AC voltage that would otherwise be applied between grid and cathode. This same technique is used with audio low level tube amplifiers.

Were talking apples, oranges and tomatoes here. Mixing behaviors and metaphors will get very confusing and deceptive. There are three ball parks to play in:

1. The vacuum or aether, and its fields and/or virtual particles
2. Electrons and nuclei that have their own fields and modes
3. Antenni or transducers, inductors, capacitors, ferrites and ceramics.

Electrons and particles seem to be forms of the vacuum energy has twisted into stable shapes (according to E=MC^2), particles can condense out of the vacuum with appropriate energy and conditions. And antenni, inductors and capacitors are made out of particles. In effect the unpaired spins of ferrites make them big (magnetic) atoms.

Atoms are dynamic systems. A photon, with an impulse-like field, causes orbital momentum change in the electron-atom system, that changes its field to cancel the photon field as it is absorbed. The fields of photons and atoms are matched, because atoms make photons (unless the atoms have a velocity spread, such as in a high-temperature/pressure laser). The atom is not like a normal tuned circuit, it dyamicaly changes tuning as it absorbs and radiates.

If the atom doesn't absorb the photon, the electron probably has some type of temporary orbit change, and re-radiates the photon. There is a time delay as energy leaves the photon field and shakes the electron-atom system. Therefore the refractive index (time delay) effects we see with glass, water and transparent materials?

Rather than orbiting particles, I like the concept of resonant ring particles joined by fields, and separated by trapped photons (stored resonant modes), such as the models at http://www.oophda.com/ and http://www.commonsensescience.org/ Nothing orbits, but strings of flux vibrate a geodesic dome of electrons around the nucleus.

Why don't atoms and photons radiate their fields away? What confines the fields? Some form of nonlinearity or extra dimensions are needed, which I was able to gather from some papers at http://xxx.lanl.gov/find :

"9902008 The energy conservation law in classical electrodynamics" (which highlights problems with the Poynting vector) and "9802039 Historical Note on Relativistic Theories of Electromagnetism".

I'm partial to considering a 4th longitudinal wave mass-time dimension, that can compress (the magnetic force), and increase density (electric force) which Paul Stowe explained here back in 7/1/99 in his "Re: what *is* magnetic permeability ?" post, which you can retrieve at Deja. The other

three dimension (normal space) only support transverse, not longitudinal waves. Charge, coulombs, equates to kilogram-seconds with a magnetic tension, and electric density. This may explain why displacement currents in space do not produce magnetic fields.

Oscillating fields trap themselves into solitons-photon waves or loop in on themselves to form soliton standing wave particles, that have increased density, which shows up as electric charge. The increased density, permitivity, trapped by the soliton particles is what sucks flux in, warps the fields around the particles.

But to make your own radio frequency particle, or electromagnetic soliton wave (and wouldn't those be usefull!!!) it would probably require quite a bit of power. Maybe some differential-geometery expert would care to help me calculate the cutoff frequency and power densities for such things?

The field around your tank might cancel an incident wave, but it better not radiate away its energy. If it is an active system, it may have a large static field that changes to cancel an incident wave, like a feedback control system. But then it can't extend over 1/2 wavelength deep without an extended structure. And what does it buy you? Probably not a better noise figure or power efficiency.

One application I thought of was a miniture phased array radar. A small, say 8 x 10" panel has ferro-ceramic spheres arranged in a grid, like a photonic crystal. In the high permitivity-permiability substrate I could shrink the size of the array. But to impedance match the array to space so it will transduce energy, I would have to have a large matching device, that would defeat the purpose of the small array.

>Your normal half-
> wave receiving dipole does exactly the same thing. It generates
> a local field which, when superposed on the incoming waves, bends
> them so that their energy "flows" into the extremely narrow
> antenna wire.

The antenna wire is a conductor which is a virual dead short for the electric field of space (x-rays above the metal plasma-freq notwithstanding). But it doesn't do much good over 1/2 wavelength

>How can a LINE act as
> a good absorber, when the waves look like a PLANE?

It can only suck in as much flux as space will permit it, by setting up opposing currents and fields, according to electrodynamics. You can model space as an LC network in this case. Its not a black hole.

> I guess an LC resonator is like a "giant iron atom" (or an iron atom is like a tuned loop antenna.)

The LC resonator will not warp space (electricaly) around it, like an atom will. It will radiate away its field.

Once again, I don't see how (atomic particles notwithstanding) the current and voltages in inductors and capacitors will cause more flux to be bent into them, although they will cancel out or transmit as well as larger elements.

> object.

Yes, the gradient has changed, no energy is not otherwise sucked in. A plot of the impedance of the sheet will reveal it is linear, a battery will just superpostion itself. If the sheet was a nonlinear semiconductor, that's different. If space is longitudinal and/or hyperdimensional, thats like a nonlinear sheet.

Both the light and atoms are probably smaller physicaly than electricaly

>At the sodium line frequency, how

The absorb it, but don't re-radiate it? Convert it too heat via atomic vibration?

I live a couple wavelengths from a VLF transmitting station that
radiates about 500kW. Do you have an estimate of the useful energy I
could expect to intercept ... with how tiny an antenna, and with what
sort of practical configuration?
>
> And you thought "crossed-field antennas" were weird! What about

"Scott Stephens" <Scott2@Mediaone.net> wrote:
> Were talking apples, oranges and tomatoes here.

True. There are the static fields associated with charges and
with the spin of charges. There are the dynamic fields of the
nearfield region. And there are the EM fields of propagating
waves. All of these are part of antenna physics, and also part
of coil/capacitor physics. If you want get into other
things besides Maxwell's equations and conventional Quantum
Physics, then that's frontier science. I'm talking
conventional science here.

> Atoms are dynamic systems. A photon, with an impulse-like field,

A photon does not have an impulse-like field, at least according
to conventional Quantum Mechanics. It has an impulse-like
interaction with atoms, but that's entirely different. For example,
a single photon can carry an entire 1MHz radio wave, yet the photon
is still pointlike (and the Fourier spectrum of such a tiny
pointlike field would be broadband rather than single-frequency.)
For photons to be pointlike, yet without ending up with a
broadband frequency spectrum, we assume that the fields
associated with photons are spread out over a huge volume of
space, yet the photons themselves are not. A photon is not like
an electron, it does not have flux lines diving into the
photon. Instead, the flux-lines of a big broad EM wave ARE
the photon, and the photon *IS* the big broad EM wave. This
involves wave/particle duality, wavefunction collapse,
and Schrodinger's Cat stuff of course.

> The atom is
> not like a normal tuned circuit, it dyamicaly changes tuning as it
absorbs
> and radiates.

That's what I'm wondering about. If I visualize an atom to be
a normal tuned circuit which also has nonlinear characteristics
AFTER it absorbs energy, then I can better understand how tiny
atoms can absorb relatively huge wavelengths of light. DURING
the absorbtion of an EM wave, I can visualize the atom as being
a coil/capacitor which surrounds itself with fields and behaves
like a conventional EM antenna.

One incorrect explanation I've heard is this: atoms can absorb
long lightwaves because atoms absorb tiny photons rather than
absorbing the waves themselves.

This is not true. It violates wave/particle duality. The
correct explanation is in the Bohren paper. Light does NOT
change into tiny photons in order to be absorbed, any more than
antenna wires absorb tiny photons rather than big broad EM
plane waves. In both cases we can think entirely in terms
of fields and forces applied to charges. As with antennas, we MUST
be able to explain light absorbtion in terms of either waves
OR particles, otherwise we've discovered a hole in Quantum
Mechanics. If you discover a situation where EM waves MUST be
made of photons rather than fields, then you've discovered
something important which is not part of normal science. The
Bohren paper shows how to explain atomic absorbtion in terms of
antennas and wave mechanics rather than particle interactions.
It's conventional science. True, it is very non-traditional.
That's why I like it! :)

> Rather than orbiting particles, I like the concept of resonant ring
> particles joined by fields, and separated by trapped photons (stored

Good analogy. Sounds analogous to LC resonators to, eh?

> >How can a LINE act as

Exactly. That's my point. The fields of the antenna act to suck
EM waves into the wire. In the example of the half-wave dipole
two things get missed:

If we could make the fields very strong, even a much
smaller receiving antenna could "suck in" EM waves.

This explains how a 0.1 nanometer atom can absorb waves
of 600 nanometers wavelength, but without needing to
include the "photon" concept in our explanations.

The inductors and capacitors do the same thing that a thin
antenna wire does. A thin antenna wire acts like a broad sheet
of absorbtive material. It does so because the fields created
by the current and voltage of the wire cause EM energy to divert
from space and flow into the wire. A one-dimensional antenna wire
can absorb a two-dimensional plane wave, but a zero-dimensional
dipole (a tiny coil or capacitor) can do the same thing for the
same reasons. If an antenna wire can erect a large "absorber
sheet" thats made of fields, then a tiny coil or capacitor can do
the same. The explanation is contained in totally conventional
field dynamics. The only unusual part is that people don't think
in these terms already!

> different. If space is longitudinal and/or hyperdimensional, thats
like a
> nonlinear sheet.

I'm not being entirely clear. The "nonlinearity" involves changes
in the shape of the linear fields, not nonlinearities in the
medium. In the carbon-sheet example, it boils down to this:
a charged capacitor absorbs energy at a greater rate than an

uncharged capacitor if the charging current is the same for
both, since energy absorbtion is just V x I. If I is
relatively constant, then a capacitor with larger V is absorbing
more energy per second. This is obvious in terms of
circuit concepts. I terms of EM field concepts, we end up
realizing that the distorted voltage fields created by the
charged capacitor will end up attracting more energy from the
carbon sheet. This is a non-traditional way to view the
situation, but it is just as correct. The "nonlinearity"
is a natural part of P = V x I.

AM loopstick antennas supposedly do just this.

I don't have two AM portable radios here, but I've heard that if
you receive a weak station with one radio, then you tune
a nearby *unpowered* radio to the same frequency, the unpowered
radio can steal some of the signal. That's the shadow effect.
Even when the power is off, there's still a tuning capacitor
connected across the loopstick. (The AGC in the radios will
probably hide this effect if strong stations are used.)

1405. Re: Weird stuff: tiny resonant antennas

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-24 00:00:00 UTC
From: Cortland Richmond <Cortland.Richmond@usa.alcatel.com>
Message-ID: <38B5AE7C.477D51C5@usa.alcatel.com>
Source record: 63117
Cross-posted to: rec.radio.amateur.homebrew,sci.physics.electromag

I understand that atom/photon interaction is a result of (or causes)
changes in the energy levels of the associated electrons. Since these energy
levels are quantized, such interactions may only occur at specific energy
levels, which explanation got Einstein the Nobel prize. However, we are
talking about photons of _light_ here, not radio. As far as I know, the
lowest frequencies at which atoms may absorb or emit energy in this manner
are in the microwave range, where the effect lets masers operate. Or used
to, until transistors got so good.

Thanks Don,

That sounds definitive and will do for me.
I should have remembered the humdingers we used to fit in audio amps all
those years ago. Also I had not taken into account the mass of the
filament. When its carrying 10A +, it needs to be pretty hefty.

Thanks to every body else who replied, by mail or NG.

Of course, it doesn't oscillate long certainly, isn't the bandwidth
inversely proportional to the pulse width?

> For photons to be pointlike, yet without ending up with a
> broadband frequency spectrum, we assume that the fields
> associated with photons are spread out over a huge volume of
> space, yet the photons themselves are not.

Yea, and an advance wave has to be emitted by the recieving atom to travel
backwards in time to the photon emitting atom, so it can emit the photon,
right? I hate that about QED. Just because the theory is so irritatingly
accurate, doesn't mean reality is realy that way. The fourier transform is
not the only one. If you can stomach extra dimensions, or longitudinal waves
and nonlinear equations, you can have solitons and Wavelets and no spooky
QED non-sense that is so well-refuted at http://www.commonsensescience.org/

> A photon is not like
> an electron, it does not have flux lines diving into the

Solitons are wave-particles that are compact and non-dispersive like
particles, and scatter and interfere like waves.

>> It can only suck in as much flux as space will permit it, by setting
>up

> smaller receiving antenna could "suck in" EM waves.

No, you missed my point! Its not the field of the antenna, its the displacement currents, the reaction fields in space that prevents more flux from flowing into the antenna. Poisson's equation.

> The inductors and capacitors do the same thing that a thin
> antenna wire does. A thin antenna wire acts like a broad sheet
> of absorbtive material. It does so because the fields created
> by the current and voltage of the wire cause EM energy to divert
> from space and flow into the wire.

I don't buy it. It is like your saying the voltage across or current through a resistor determines its resistance. Of course the resistance of a resistor can be defined by V/I, but when we talk about a given resistor it is typicaly the cause and the current the effect of the voltage across it. Similarly, the gain, radiation resistance, of a given metal dipole, or inductor/capacitor combination in space will not be determined by the voltage across or current through it.

True the fields surrounding it may cancel out the field in a large field around it. So you could contrive a scenario where a tiny LC resonator with lots of power cancels out (absorbs, if you will) the same incident wave a much larger dipole can. But this is not the same as an atom sucking in the field-space around it.

When the energy density, rates of change and field configurations are favorable for solitons, the Poynting vector of the soliton's field bends the Poynting vector of incident energy into the soliton, very similar to relativistic distortions. Now you might think I am agreeing with you (I guess I am) at this point, but the power density is such for particles and photons that I don't think you will be doing it short of microwave and kilojoule regimes. The fringe conspiracy stuff I read on Keely-net says the Russians need power plants to fire up their scalar toys ;-)

1409. Re: Determine Inductor value of coil

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-24 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <38B5D0FD.C5D4B6FC@agilent.com>
Source record: 63121

I've always heard it as a = the mean radius in inches, that is, the radius to the center of the wire. Assuming that's true, a = 1/16 + 0.016/2 = 0.0705 inches. b = 14*0.0159" = 0.2226" and the formula suggests L = 0.34uH when I run it on my calculator. I'm not sure why this disagrees so much with Luiz' result, but suspect a math error somewhere.

Some time ago, I did some comparisons of the simple formula Luiz posted with a supposedly very accurate formula, rather much more complicated, and found the differences exceeded 5% only with extreme ratios of a:b. Where a:b is between about 1:5 and 1:1, the differences were in the 1% range, IIRC. Even at very extreme ratios of a:b the differences were never as great as 10%. However, there are some things to be aware of:
--That's for just the coil, no leads
--It doesn't include the effects of shielding (which will lower the inductance) or core materials other than air
--It doesn't include the effects of distributed capacitance (which will be significant for closewound coils) which may make the effective inductance appear to be less (because it takes less external capacitance to resonate the coil).

Cheers,
Tom

Hi Rico,
What about a full bridge instead a push-pull?
With a bridge the maximum voltage the Mosfets handle would be the input
peak voltage.
The energy in leakage inductance could be absorbed by the input
capacitor filter.
You don't need to use snubber circuits.
The transformer primary is easier to wind.
The push-pull tendency to unbalance can be avoided.
Of course there are some disadvantages. Four mosfets and more elaborated
driver.
I suggest you a voltage mode controller with a totem output that can be
found with application notes in Unitrode/Texas, Motorola,Philips,
National, and others.

This has been niggling at me for a few days now and I can't think of an answer.

Why is it that in a GG linear using a directly heated filament valve there is no 50/60c/s mains hum superimposed on the signal?

coils.
==========
If he has the handbook or ready access to it, he wouldn't be asking
the question. In any case the handbook is not the bible. It has many
misleading errors.

The formula already given by someone else -

L = Square(n*a) / (9*a + 10 *b) microhenrys

is accurate enough, where n is the number of turns, a is the radius of
the winding (half distance between opposite wire centres), b is the
length of the winding (number of touching turns times wire diameter),
all in inches.

1418. Re: Tank Q and Plate Current

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-25 00:00:00 UTC
From: Tom Bruhns <tom_bruhns@agilent.com>
Message-ID: <38B6D238.E47BD6A5@agilent.com>
Source record: 63045

I think the question comes down to, "what exactly does the 1A current rating mean?" I'd say that rating is for folk who look at DC meters, not ones that get into wondering what the circulating RF currents might be doing.

To begin with, the circulating tank current is mostly NOT going through the cathode; there is very little plate-to-cathode capacitance, given a grounded grid. Next: why maximum current ratings? Too much voltage causes arcing, x-rays, and the like; too much power causes melting. I can see that too much DC current emitted from the cathode can cause troubles for the emission surface. But we're talking about current in the plate here, and returned through the grid. Certainly a consideration might be the heating effects of the current on the grid: you don't want the grid to warp or to get so hot it starts having significant emission itself. So...though the circulating RF current is worth considering, I don't think the 1A DC tube rating is the right thing to be measuring it against.

Cheers,
Tom

> external capacitance to resonate the coil).

I guess to make much sense, that should read, "appear to be more".
Duh.

Also, I should have said "a couple of percent" instead of "1 percent"
for a:b ratios near unity. Still, a couple percent should be adequate
almost all ham homebrew applications. If you need closer than that you
better plan a way to trim the inductance anyway.

Cheers,
Tom

Hi SSparky.
Just a note on those microwawe HV transformers........They supersaturate the
core so run the primary at about 90 volts.

I disagree...regens are NOT tricky and can be extremely sensitive and can be built selective enough to cut the sidebands off a signal. Search the net....some fine examples are out there and they are fun to build.

No, I'm not saying radio and light are different. Only that the absorption
of photons by atoms is limited to energy levels corresponding to states
their orbital electrons can occupy (the photoelectric effect).
Consequently, radio signals, unless of sufficiently high frequency specific
to the elements concerned, won't be absorbed in this way.

Actually, the above is incomplete. There IS an effect, in which atoms
subjected to a magnetic field will absorb radio waves of specific
frequencies at lower ranges, but this involves (I think) resonating with
the spin of protons in the nucleus. This is used in NMR imaging. I don't
know what frequency a "normal" earth magnetic field would resonate, but I
understand 70 MHz is typical for an NMR machine, with its much stronger
magnetic field.

I'm in the middle of building an FET version of a regenerative receiver. (See http://www.mines.uidaho.edu/~keng/sch/ which includes the Lindsay and several other regenerative receivers.)

I suspect they may indeed be tricky, based on the comments from my elmer. But he has offered to help check the sensitivity, etc., so I'm hopeful I can get it to work. I'll let you know.

You'll probably get more competent advice from the Glowbugs listserve. See http://www.qsl.net/n6ev/GBlist.html for instructions on how to subscribe.

1427. Need HUMMM advice

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-25 00:00:00 UTC
From: Ron H <rnharsh@visi.com>
Message-ID: <kKFt4.1664$%A3.36470@ptah.visi.com>
Source record: 63054
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

OBSERVATION
I am hearing a HUMmmm in my headphones when the rig is first keyed and on each key closure for three or four characters. I also noticed that the power output starts off a little higher and drops a few watts as the hum goes away.

QUESTION
Could this be a function of the capacitive power supply filter on the final plate supply? No choke, just caps.....

Should I be concerned???

Likewise. Threads like this make me particularly frustrated at the encroachment of proprietary web-based message boards onto Usenet's territory.

Sometime within the next few years, I'll probably find myself surfing DejaNews looking for Monty's post and the others in this thread. If the thread had taken place on some random Web-based forum somewhere, the information would be completely out of reach.

Does this mean you believe that light is fundamentally different
than radio? :)

The big question is this: when atoms absorb light, is the process
at all similar to the way an electrically small resonant loop
antenna absorbs radio waves? Well, electron shells of the atoms
have big quanta, while the quantized states of a macroscopic
metal antenna are incredibly small. That doesn't mean that atoms
only use photons, while radio antennas only use waves. Wave/
particle duality applies to both, and no matter how few photons
are on the fly, they still form an extended electromagnetic
waves. For this reason we can can talk about light absorbtion
in terms of fields and resonance, rather than in terms of photons
and electron states. The uniform size of an atom's energy
states corresponds to the narrow bandwith of a resonant antenna.
And the enhanced "effective area" of a loop antenna at
resonance corresponds to the enhanced "photon collision
cross-section" area of an atom when the photons have the same
energy as the atom's internal electron transistions.

> As far as I know, the
> lowest frequencies at which atoms may absorb or emit energy in this
manner
> are in the microwave range, where the effect lets masers operate. Or
used
> to, until transistors got so good.

Right. But look how small an ammonia molecule is when compared
to the microwave wavelength. How can small atoms absorb more
than the radiation incident upon them? The Bohren paper points
out that the same question also applies to electrically-small
resonant antennas. Because strong AC fields occur at
resonance, small antennas can swell up in "size" until

they resemble quarter-wave dipoles. If atoms behave in the same way, then at resonance an atom will cast a shadow which resembles the shadow of a quarter wave dipole, even though the atom is far, far smaller.

I wonder how big a wavelength a molecule can absorb? Is the cutoff really up in the microwave band? If for some reason a molecule had a low-energy electron transition, then that molecule will be resonant at that low frequency, and will absorb waves having that wavelength, even if the wavelength is immensely larger than the diameter of the molecule. Since the resonant molecule can be physically much smaller than a quarter wavelength, in principle a single molecule could absorb AM radio or 60Hz radiation.

Separate topic: I hear that head shields for cellphone users are selling for $50 a pop. On the one hand, maybe there's a physical mechanism whereby 900MHz radiation can affect chemical reactions. On the other hand, I bet somebody eventually starts selling "ferrite ointment" which you can slather on the side of your head to keep the nasty EMFs out of your brain!

The shadowing effect is only noticed when they are very close. Their actual capture area is always much smaller than the theoretical figure because it is impossible to extract the available power since the optimum load impedance is impossible to achieve. Shadowing occurs when the mutual impedance between two antennas is of comparable magnitude to the self-impedance of either. For loopstick antennas the self-impedance is dominated by the large reactance, and the mutual impedance is small unless they are very close. There can be an effect when you put two radios close together.

Tom - assuming the station is on 17kHz you are 35km away, and with 500kW radiated you can expect the field intensity to be 190 millivolts per metre.

With a 10m-high monopole receiving antenna in your garden the open-circuit voltage will be about 0.9 volts. But - the source impedance for this voltage
will be about (0.0001 - j200000) ohms, which is determined by the radiation resistance and the capacitance of the antenna. If you can match perfectly to this
impedance the available power is 2kW. The catch is, it's impossible to provide
the right load impedance, so, practically, the extracted power is negligible.
Similar arguments apply to a loop antenna.
Alan

1444. FS 4CX800A MP final days

I am selling Svetlana Russian Military matched pairs of the 4CX800A tubes. This is a special purchase group of tubes, and there are very few of these matched pairs left. These tubes are nos, but carry my own 90 day warranty. These tubes have a green indicator strip on the side of each tube. These strips turn brown when the tubes are used. All of these tubes still have the green strip. When these are gone the price will go back to $125.00 per tube. I am selling these tubes as long as the supply last for $190.00 for a matched pair plus shipping. I will ship anywhere in the world. You can call me at 256-593-0164 or preferably just send me an email.

1450. Re: Tank Q and Plate Current

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-25 00:00:00 UTC
From: stoskopf@tri.NET
Message-ID: <38B6A34D.1C9B5EEB@tri.net>
Source record: 63143

Just to straighten out my understanding of plate and tank currents:

Suppose we have a tube rated at plate and cathode max current of 1 A. GG output capacity of 30 pF. Operating on 160M with an external tank Q of 10. Assume tank added capacity is 270 pF. (Just picking easy numbers) So when we drive the tube to a peak current of 1A, circulating current thru the added capacitor is 9A and 1A thru the tube cap. ? Tube can take that at max ratings.

Now, lets move to 6 M and we can no longer use an external capacitor so we either just use the inductor tuned by the tube cap or do what is commonly done on 2M amps, feed in the B+ from a center tap in the inductor and add a series cap to the other end to mimic a push pull configuration. Circuit is more manageable.

Instead of a parallel tuned circuit circulating 9 A outside the tube, we have a series circuit with the tube in the whole current loop (or is it a parallel circuit with the capacitor consisting of the tube and tuning cap in series ..resulting in roughly half the tube cap in most applications).

In the latter case, if the Q is still 10, 10A are now flowing thru the tube and it is rated at 1A. In the former series case, with a Q of 10, the current has to be 1A and since we are feeding B+ to the inductor at the center, the current is fixed so the voltage developed is 10 X the B+, assuming the tube driven to full on and cutoff. With a 3 KV B+, 30 KV at the plate and good bye tube (unless you are using one of the pulse type tubes.).

Obviously the bumble bee can't fly! Comments?

Sorry for the length and probably obvious question. Took my Novice in the 50s when you had to draw schematics on the exam and my Extra in the 70s, so this is probably question #1 on the new exams.

1451. Help- Plans for Simple Receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-25 00:00:00 UTC
From: paulygman@my-deja.com
Message-ID: <896gic$1q4$1@nnrp1.deja.com>
Source record: 63144

I would like to build a simple receiver,1-3 tubes, not a kit. But first I need a good set of plans, perferably in the form of a magizine construction articile,like from an old popular electronics issue. Has anyone previously built one. Any advice would be helpful. I am searching for plans. I got a book from Lindsay on Building Your First Regenative Receiver and also looked at plans on the web called "One Compactron Reciever" Freinds say a regenetive reciever is tricky and not worth to build, but a heteradyne seems more complicated. Does anyone have first hand experience with building a simple reciever. Does anyone know of magazine articules on the subject. My county library here in New Jersey has loads of old popular electronics, 73 and QST, but no real index to construction articules.
Thanks

Source record: 63057

Paul: Sounds like you are a good candidate for the Mighty Midget Receiver Corps. Superhet. 3 6U8 tubes. Covers 80 and 40. SSB, CW and AM. You can do some short wave listening with it too. Check out the AM portion of my web site:

http://www.erols.com/wmeara

Good luck. Hang in there. The satisfaction that comes from listening to a homebrew rx more than makes up for the frustrations that you will encounter in the building process. And the frustrations are educational.

I think you are right to avoid regens, at least at first. I have great respect for regen builders, but I think that a simple, single conversion superhet is actually easier to get working properly.

1455. OT: TEK 485 Scope repair

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-26 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <38B71C5D.F6A6FA47@lafn.org>
Source record: 63060

Hi,

My QRP homebrew favorite test gear has failed.

Last week, my TEK 485 scope suddenly began having wildly varying
brightness when started cold. Today, the scope won't start, panels
lamps are all off, and I hear only a slow "tick tick" sound.
Power Supply probably seeing a fault and shutting down repeatedly.

I am looking for a local place to repair,
local to San Fernando Valley, near Los Angeles.
Appreciate any recommendations.

Thank you for off topic bandwidth.
This scope is a GREAT piece of gear.
I am lost without my FAVORITE scope.
73, W6MIK

I also know a guy who extracted power to run lightbulbs etc from
a nearby am transmitter.

If you have a big resonant loop, and the voltage builds up, then
this also implies the *current* builds up.

Right, so if you have narrowband light such as laser light, it
means that each photon must be very long compared to the
wavelength. And each photon must be extremely wide if it's to
hit both telescopes of a small-baseline stellar interferometer.
(I hear that the photons from Beteleguse act like they're about
10 ft across!) I don't think you can stretch the "photon"
concept until the photons resemble electromagnetic waves, since
an EM wave really can be huge in extent, even for optical
frequencies.

> Yea, and an advance wave has to be emitted by the recieving atom to

I've heard these issues mentioned, but never heard about
the details. My math is fairly weak (being into digital,
rather than analog electronics!) :)

Ah, I think I'm saying "flux" meaning energy flux, and you're
talking about e-field and b-field flux. You're right, the
resonant antenna doesn't suck in flux lines of e-fields or
b-fields. Instead it does some weird things to those fields
which end up sucking in Poynting-vector flux into the
antenna. A small, resonant antenna acts ANALOGOUS to iron or
ferroelectric, but it doesn't concentrate the field lines.
Instead it ends up concentrating the Poynting vector flux. It
does so by "sculpting" the e-fields and b-fields of the
incoming EM waves in order to direct the flow of energy
inwards towards the antenna.

it.

Yep, it's weird and counterintuitive. But it's not nonlinear.
It's like the example I gave with the capacitor: if you
charge a capacitor at a 1mA rate, with 1 volt across the
capacitor, then you're pumping in a millijoule of energy per
second into the capacitor. But if you let the voltage across
the capacitor rise to 2 volts, then you're pumping in 2mJ
per second. Suppose the capacitor is being charged by a 100
volt power supply with a 100k resistor in series. The higher
you let the capacitor voltage rise, the higher grows the energy
flow into the capacitor. In the case of small resonant
antennas, if we let the AC fields around the antenna build
up to a high level, then the antenna gathers energy at a higher

and higher rate, but only until the surrounding fields start
to affect the "power supply" and prevent further gains in
power reception. This occurs when the fields generated by
the antenna become significant at 1/4 wavelength, and the
antenna starts radiating as much as it absorbs.

> Similarly, the gain, radiation resistance, of a given metal dipole, or
> inductor/capacitor combination in space will not be determined by the
> voltage across or current through it.
> True the fields surrounding it may cancel out the field in a large
field
> around it. So you could contrive a scenario where a tiny LC resonator
with
> lots of power cancels out (absorbs, if you will) the same incident
wave a
> much larger dipole can.

Right. Electrically small antennas can "act large" if they're
tuned to resonance, and the effect occurs only if the AC
fields generated by the antenna are synchronized to the fields
of the incoming waves. But the antenna's fields are created by
the voltage and current in the coil/capacitor, so it forces me to
say that the voltage and current causes the effective size of
the antenna to be much larger than the physical size, but ONLY if
the voltage and current waveforms are locked in phase to those of
the incoming waves. This occurs naturally in a resonant
circuit, so we don't have to artifically drive a coil with a
power supply in order to see the "energy sucking" effect (but
we could do so if we wanted to.)

> But this is not the same as an atom sucking in the
> field-space around it.

Why not? That C. Bohren paper points out that a tiny metal
particle does "suck energy" from the surrounding space because
the surface plasmons are resonant with the incoming waves.
If the same applies to individual atoms, then when an EM wave
hits an atom, and one of the electron clouds is resonant at
that frequency, then the electron cloud starts sloshing more
and more, which creates a larger and larger AC field around the
atom, which diverts more and more wave-energy towards the
atom... until the electron suddenly changes state. This
doesn't explain most of QM, but it does explain how a 0.1nM atom
can strongly interact with 600nM radiation, as if the diameter
of the atom was a quarter wavelength across instead of hundreds
of times smaller.

> Russians need power plants to fire up their scalar toys ;-)

If this happens, it means that the fields must be intense enough
to make space go nonlinear. (Don't solitons only travel in
a nonlinear medium?) If the vacuum is nonlinear at high
field strengths, then you can probably make atoms out of
collapsing hunks of EM radiation.

Small resonant antennas are "nonlinear" only in the sense that
an incoming EM wave sees all matter as a nonlinearity in space.
If the hunk of matter happens to be a resonant circuit, it acts
even more "nonlinear" than the surrounding matter.

We're in agreement. If a molecule for some reason had a low-
energy state transition, it could receive radio waves, even
though the "antenna" is the size of a molecule. The energy
per photon would be extremely low. Maybe that's why we
never hear about such things: if the energy per photon is
far less than the energy stored in a chemical bond, then
longwave EM wouldn't be able to break bonds directly, and
radio waves wouldn't affect chemistry. This would only be
true if there were no effects involving the absorbtion of
multiple photons, or effects where a tiny nudge could have
a big effect on a chemical reaction already under way.

Proton precession magnetometers use the proton spin of the H
in water molecules, and the frequency is around 2100Hz. This
was in an old THE AMATEUR SCIENTIST project in SciAm, where a
bottle of water with a coil around it produced a "ding" sound
after amplification. This is a case where you can directly
hear the resonant frequency of atoms, but it doesn't really
correspond to photon absorbtion by electron shells.

I've done it, sought of. I wound about 14 turns on a cardboard box
and connected to a 415pF tuning cap, so it resonated 600-1600kHz.

Now put a ferrite rod tranny in the box, tuned to a weak station.
Now adjust the box tuning cap to resonate the big coil. Your station
will increase by 20-40dB ! (Hint: orient the box coil in the right
direction, and use thickish automotive wire for the coil).

By connecting an OA91 diode, resistor, and crystal earphone, i could
get 5 sharply tuned stations without needing an external antenna or
earth.

1460. Re: Car batteries; and the charging of

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-26 00:00:00 UTC
From: maddog@io.com
Message-ID: <38b73f87.163474244@news.io.com>
Source record: 63065

In recent conversations with EXIDE engineers, I was told the *safest* thing to do to assure maximum battery life (when using sealed lead-acid or gell-cells) is to charge with a 13.5- 13.8 Volt regulated, current limited power supply, and to leave the battery charging at all times (when not actually in use). This was their reasoning:

All sealed batteries have pressure vents seals in them. These are one-time seals that vent-open if, for whatever reason, pressure builds above a certain point in the battery. Usually, this happens as a result of over-temperature or out-gassing. Over-temperature can be caused by over-charging, or by failing to limit the charging current to manufacturer's limits. Out-gassing, which is the creation of gases in the electrolytic suspension at a rate faster than can be absorbed by the battery chemistry, is usually caused by overcharging. In the case of gell-cells, the point where outgassing begins to occur is when the charging voltage exceeds 14.4 volts (+/-). Sometimes sealed lead-acid cells are rated at 14.8 V, sometimes as low as 14.4 (according to manufacture). The end result is that once the pressure vent is open, the electrolyte will dry. For gelled electrolyte, the results can be radical reduction in performance and capacity in a relatively short length of time (< 6 mos). For sealed lead acid, the reduction might not be noticed for a year. The end result is that the battery electrolyte becomes low or inneffective, and sulfation is accelerated. For gelled and sealed lead-acid batteries, this amounts to shortened life, and useless batteries.

By using a fixed 13.5-13.8 Volt charging circuit with current limiting, the battery never gets close to those breakdown conditions. This doesn't mean it will last forever (after 3 years at room temperature, a GOOD battery, properly maintained will probably only have 40-50 % of it's original capacity). What do you give up by not over-charging to 14.4 V, followed by a float charge? Very little. A lead acid battery, charged at a fixed 13.8 volts, will probably have 95% of its rated capacity (overcharging brings it to 100%). Also, it may take 15-25% longer for the battery to reach that 95% level, than if you applied 14.4 V. Usually these factors are not problematic in ham radio service.

If you don't use current limiting, the current will be limited by the battery effective charging resistance, which like all resistors generates heat. Some manufacturers (though not many) claim to have "self-limiting" charge currents. I'm sure there is a performance trade-off for this feature, probably effective discharge resistance (i.e., source impedance). Most expect the charge circuit to limit the

current. In almost all cases, the design limit for charge currents is 15-25% of battery capacity (typically, 20%). As an example, a 30 Amp-hour capacity battery should be limited to 30 x 20% = 6 Amps max. Excess peak charge currents can also have the effect of mechanically breaking the cell-to-cell connections inside the battery, which are usually designed to be as small as possible for the rated service currents, so as not to take much room inside the battery case.

Sulfation is the major and most common cause of battery failure or reduction in capacity. Even a properly maintained battery sulfates gradually, and this is why the total capacity gradually decreases. Several things can accelerate that process however, and one of them is undercharged electrolyte. The increase in rate of sulfation is significantly increased when battery voltage is allowed to discharge below about 8-9 volts (for a 12 V battery), or if it is left below about 11 Volts for any length of time (even days or weeks). I recently had this experience with a brand new (two-month old) car battery, when I left the dome light on during a 2-1/2 week vacation. The battery discharged to about 2 volts, and never took a charge again. So you'll get the longest life out of a battery by keeping it charging at all times, when not actually drawing current from it, or at least charging it immediately after discharge, and once-a-month or so afterwards. This is often easy to do for ham radio applications. (Don't apply this same philosophy to NiCads batteries)

There have been some interesting devices that apply overcurrent pulses to batteries to partially break down the sulfation. Some are quite effective, some are wive's tales. I'm not sure how to sort them out. One that I've NOT tried but appears may be effective in reversing sulfation damage is built by Solartech:

http://www.solartech.com/index2.htm

That site also has a number of interesting papers about battery chemistry, which you may also enjoy. In any case, most methods are not "quick" (hours), and not particularly friendly to someone wanting to use a communication receiver (hash noise).

Hope this helps!

Frequency is statistical, an average of many events over time. A photon is a particle, an individual instance. Better to specify its energy. Solitons have a width, roughly equivalent to frequency.

> And each photon must be extremely wide if it's to
> hit both telescopes of a small-baseline stellar interferometer.

I don't buy it. I think there are lots of soliton-photons being emitted by atoms in the distant star that scatter, interfere with each other. Next you will protest that the double-slit experiment proves that a single photon must travel through both slits. But consider the vacuum or aether as a transmission line or multi-mode waveguide supporting solitons. If you affect one of the paths, you actualy detune the transmission line, and affect the source and paths for coherent soliton or wave emissions. So you can account for spooky QED stuff like tunneling, entanglement and Hiesenburg exclusion with solitons, or more properly a vacuum or aether.

>> Yea, and an advance wave has to be emitted by the recieving atom to
>travel
>> backwards in time to the photon emitting atom, so it can emit the
>photon,
>> right? I hate that about QED.
>
> I've heard these issues mentioned, but never heard about
> the details. My math is fairly weak (being into digital,
> rather than analog electronics!) :)

An interesting explanation is at http://chaos.fullerton.edu/~jimw/general/inertia/index.html 3/4 of the page down. Not that I'm a true believer of transient mass fluctuations, but the LANL paper "9902008 The energy conservation law in classical electrodynamics" and CSS point out some problems with the Standard Model. It is also mentioned in (IIRC) in the Relativity FAQ. It has to do with the

finite propagation speed of the Lorentz force, and gravity has a similar problem. Gravity and EM force points at where the attractor was, not is, so orbits can decay, and EM solutions blow up. By adding dynamic reaction forces, the systems stabilize and don't decay. But at relativistic energies, particle self-energies change making for some very difficult, chaotic and questionable predictions by the Standard Model.

> capacitor,

That would require a current source composed of a dynamic, nonlinear, resistance.

> then you're pumping in a millijoule of energy per
> second into the capacitor.

The current source to charge that capacitor might have used 1 volt, but you failed to spec the capacitor which I must assume was constant, as E=1/2 CV^2. Now if C is constant, and the voltage is constant, the energy is constant too.

> But if you let the voltage across
> the capacitor rise to 2 volts, then you're pumping in 2mJ
> per second.

You must be talking about a capacitor that is dynamicaly changing capacitance, that is nonlinear, because you keep a constant voltage across a capacitor as you increase the stored energy at a linear rate.

> In the case of small resonant
> antennas, if we let the AC fields around the antenna build
> up to a high level, then the antenna gathers energy at a higher
> and higher rate, but only until the surrounding fields start
> to affect the "power supply" and prevent further gains in
> power reception.

Now we're talking about a different situation, with an LC and sinusoid. The LC will 'ring up', initialy presenting a greater load to a source delivering a constant voltage. Now I see what you mean, I think. You mean that the power extracted from the incident field is dependant on the energy in the LC tank. Considering a sinusoidal field potential, and a sinusoidal tank

voltage of equal value, there be no energy or complete energy extracted
depending on relative phases, of 0 or 180 degrees respectively. OK.

This has nothing to do with "concentrating the Poynting vector
flux..."sculpting" the e-fields and b-fields of the
incoming EM waves in order to direct the flow of energy inwards towards the
antenna." Or, IMHO what goes on with atoms and photons. Your arguement
involve changing the potential difference across circuit elements. I think
what happens with atoms and photons is a changing of the properties of the
vacuum, a warping of space-time for the EM poynting vector and dynamic E and
B fields.

> But the antenna's fields are created by

Right, ok.

> This occurs naturally in a resonant
> circuit, so we don't have to artifically drive a coil with a
> power supply in order to see the "energy sucking" effect (but
> we could do so if we wanted to.)

I don't think so. If you don't criticaly damp, that is conjugate match,
absorb all the energy from the LC antenna, it
will not cancel the field as you think. If you let it ring up to the
incident field potential and cease to absorb power. How do you get a 180
degree phase shift field without constantly supplying the energy to do it,
and then radiating away that energy? It sounds like your talking about
active signal cancellation. What wonderfull stealth that trick would make!

>> But this is not the same as an atom sucking in the
>> field-space around it.
>
> Why not?

A photon field has that many cycles?

> which creates a larger and larger AC field around the
> atom, which diverts more and more wave-energy towards the
> atom... until the electron suddenly changes state.

Consider an electron with its relatively powerfull magnetic and electric
potential, and its wavefunction. An incident photon impulse causes it to
ride the wave, and if the (DeBroglie?) wavelength is in phase, it gets stuck

in a new orbit, otherwise it falls. As the electron moves, it actively cancels the incident field with its powerfull potential, and stores it in the potential energy of its orbit (or resonance). Or consider a Lucas ring electron vibrating lines of flux around between the nucleous and its neighbor electrons. Not quite as simple as the classical case, but I think more realistic.

>> Russians need power plants to fire up their scalar toys ;-)

> If this happens, it means that the fields must be intense enough
> to make space go nonlinear. (Don't solitons only travel in
> a nonlinear medium?)

Yes, sort of. Nonlinear as in changing Mu0 or E0, as ferromagnetic and ferroelectric ceramics do near saturation, no. You would see lasers intermodulating and frequency dispersion and stuff. The nonlinearity I'm talking about is like the nonlinearity of the Lorentz transform in Special Relativity, where fields are bent and distorted, as energy (Poynting vector) changes from dispersing as transverse waves in 3d space to higher dimensional longitudinal waves, which in turn can warp the transverse waves. Energy knots can form. Fast rates of change are required, as we don't see EM solitons short of Maser emissions (that I'm aware of).

> If the vacuum is nonlinear at high
> field strengths, then you can probably make atoms out of
> collapsing hunks of EM radiation.

Yep. Ever year of Beamstraalung (not bremstraalung, breaking radiation)? Intense particle beams can shear the vacuum, spawing particles like the turbulence in fluid wake.

> Small resonant antennas are "nonlinear" only in the sense that
> an incoming EM wave sees all matter as a nonlinearity in space.
> If the hunk of matter happens to be a resonant circuit, it acts
> even more "nonlinear" than the surrounding matter.

I think you are confusing the transient (or forced) response of a linear, LC circuit with different phenomena with atoms.

As the output power is higher during the hum, it is possible that the
power supply filtering is not being enough for this big power. As it
diminishes filter becomes good.
I'd suggest you to investigate the RF power circuits to see why this
power increase occurs. You haven't told whether it is a tube or
transistor rig but to measure the bias circuit to see whether it shows
any change during the problem is a good idea , I think.

Cathode-driven means the grids are grounded. Grid-driven means the cathode is RF-grounded.

> If I go grid-driven, how do I calculate the correct amount of grid
> 'swamping'. (The transmitters I have currently run single 6146 finals at
> about 90 W input)

The idea is not to allow the grid to go into the positive region at the drive peak. At the same time, the correct idle current must be maintained, so the whole thing is like a balancing act. . With a 3kV anode supply and a 500v screen supply, the constant-current curves show that roughly -130v is needed to obtain c. 30mA of Zero Signal Anode Current (ZSAC). For Class AB1 linear operation, to develop 130v-pk across a 50-ohm grid-termination, 169w PEP is needed. (Ohms' Law) With a 200-ohm grid termination and a 1 to 4 broadband transformer, to develop 130v-peak, c. 70 w is needed. A diagram on my Web site shows such an arrangement. My guess is that each 4-65A should be able to produce approx 250w in linear service. Thus, for a legal limit 4-65A amp., one would need a half dozen of 'em in parallel. There is an old-wives' tale about too much C for 10m operation with paralleled tubes. However, double the number of tubes and the required C-tune doubles. // I would use neutralization above 7.3MHz.

> In either case, any other configuration tips that are particular to these
> tubes from anyone with experience with them would be most welcome as well.
> (like their favorite plate / grid voltages, etc)
>
The max. key-down linear service ratings are 3kV on the anode and 600v on the screen. However, since the plate-modulated rating is 2500v max., (5000v-peak) my guess is that 4000v would be ok for SSB - as long as tuneup was accomplished with 50wpm dits or a tuning pulser.

Folks, I have one of these radios that my wife purchased for my birthday last month. It seems to work fine on all modes. My only complaint is that I have never seen the s meater rise above s5. The receiver seems to receive just fine.

Does anyone have a mod for this radio that will allow you to transmit cw (my favorite mode) or open up for 11 meters. I know this would be a new low but its pretty boring on the road (2 hrs daily) when the band is closed. Ed

Hi Norm,
The best way I figure, is to open the back of the mic, and look at where the wires are connnected to. I would figure it's an electret mic by your discription, but opening it up would confirm, and it sounds like you have the PTT to the red wire confirmed. Using the black wire as your ground reference is not usually a good idea, as it just may be the other side of teh mic cartridge. (i.e. green and redd may be PTT, etc.)
Anyway, you didn't mention if you had the wiring connections for the IC725, so here they are in case you dont.
(8 pin)
1- Mic Input
2- +8V DC output (be careful with this one, you can pop a regulator of you short it.)
3- Freq up/down
4- No Connection
5- PTT
6- Gnd (PTT)
7- Gnd (Mic)
8- Audio out.

I sure hope this helps!

- Fred VE7EJ

HAMFEST March 5, 2000 - Lindenhurst, LI

GREAT SOUTH BAY AMATEUR RADIO CLUB & SUFFOLK COUNTY RADIO CLUB
ARRL APPROVED LONG ISLAND HAMFEST - March 5, 2000

On March 5, 2000 the Great South Bay Amateur Radio Club & Suffolk County Radio Club will again sponsor an indoor Hamfest. The location will be at the:

Knights of Columbus
400 South Broadway
Lindenhurst, Long Island, NY

There will be radio equipment, electronic components, computers and accessories, software, books, technical manuals, ARRL information, Amateur Radio License Exams, Door Prizes. General admission is $6.00.
Free Admission for spouses and children under 12.

VE - ARRL - 12:00 NOON
For exam candidates please remember to bring your original FCC Amateur Radio license (if licensed), any C.S.C.E. forms that are pending, plus a photocopy of each, pens, calculator, formal form of ID (preferably photo ID),
and the examination fee, to the exam session. 1999 ARRL/VEC fee is $ 6.45, exact change is appreciated. Novice exams are free.
The VE team is from ISLIP ARES Group and GSBARC. Thanks guys.

PLEASE NOTE: The VE session will be held at the Babylon Town EOC.
200 E Sunrise HWY, North Lindenhurst, NY.

Vendor information - Walter Wenzel KA2RGI at (631)957-0218.
Email info@gsbarc.org

Talk-in will be via W2GSB Repeater on 146.685 4Z(136.5) PL.

Food Service during the Hamfest will be provided by members of the Knights of Columbus Council.

Information is also available during the GSBARC 2 meter info net every Monday evening at 7:00 pm on the W2GSB repeater, 146.685 -600 4Z(136.5) PL required. You may also write to:

Without digging for it, and I'm not even sure I have the schematic around,
I'll make a guess. If it uses a 6U8A pentode/triode in one package, then
I can make a good guess. The pentode is the product detector, and the
triode is the BFO. The inter-electrode capacitance is what couples the
BFO signal into the product detector.

I have a 1961 Handbook in front of me, and it has a simple superhet
using a 6U8A as product detector and BFO. The article even mentions
that "stray coupling at the socket and in the tube provides sufficient
coupling".

Good idea. CBers will be very pleased to see the fine example of compliance with the FCC rules and regulations. It will difinately encourage them to join our ranks.
Are you a licensed amateur radio operator?

1480. Active Stealth (was Re: Weird stuff: tiny resonant antennas)

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-02-26 00:00:00 UTC
From: Scott Stephens <Scott2@Mediaone.net>
Message-ID: <oFYt4.11898$84.365594@elnws01>
Source record: 63085
Cross-posted to: rec.radio.amateur.homebrew,sci.physics.electromag

Consider a highly resonant LC tank that is coupled to an incident field. The tank initialy acts as a short to the field, absorbing power as it rings up, until it is oscillating with the same potential as the incident field and absorbing no more energy (its losses not withstanding).

Now if it could be switched, inverted 180 degrees in phase, it would indeed cancel the field around it. That is called active noise cancelation. The trick is to generate the conjugate field, quickly without becoming an oscillator.

Consider a small spiral patch antenna that covers an octave. It is placed on a very dissipative ferrite-graphite composite, 1/2 wavelength (mid-band) thick. Underneath is another spiral patch. The spiral patch on top is the input port, the patch on bottom the output port, with an amplifier MMIC in between. The system is now a feedback amplifier, designed to cancel the incident field.

An aircraft would be covered with this oscillator skin. Each oscillator is a sandwich of a top and bottom conical spiral with graphite in between. There are multiple layers of these spirals, in a 3 dimensional fractal pattern, to cover decades of radar illumination.

Sound workable?

Scott

1481. Re: Simple broadening of CW receiver

Newsgroup: rec.radio.amateur.homebrew

Message-ID: <blackm00-2602002048000001@dialup-282.hip.cam.org>
Source record: 63086

Of course, you give up single signal selectivity, but of course that
wasn't a feature of superhets until some years after Armstrong
came up with the idea of superheterodyne.

Or to put it in modern terms, you end up with a direct conversion
receiver with converter ahead of it.

THat doesn't negate the idea, and one probably is better off with
such a scheme and later improving things, than not starting in
the first place.

There was an article in Ham Radio towards the end of it's life, I
don't have the article handy, about making ladder filters with
vriable selectivity. The guy switched the capacitors to give
both CW and phone selectivity. He went into the details of the
project, so it is a good basis for further experimentation.

Having just passed my extra upgrade last week, I'd like to celebrate with the purchase of a good QRP kit. I'd prefer something with SSB/voice, but I'm not ruling out CW only rigs. I've heard lots of good press about the DSW-40, but wonder what else is out there. This would also be my first kit, although I've been soldering for years.

You must be right but, as you can note, I wrote the source of the
information at my message end; The Radio Amateurs Handbook drawing of
the coil shows clearly 'a' as the external value of the measure, not the
average one. About the final value, I asked the original message issuer
to recalculate it because I had done the calculus only for once.

Hi Paul,

> little radio to work like a real duples station so working the UO-14 FM,
up
> 145.975Mhz and down 435.070Mhz? It is somehow more easy to do the job if
you
> are abel to receive your own signal.

Well, the radio is NOT full duplex, so you will never be able to hear your own signal's unless one of the birds is in "parrot" mode. But I use my FT-50 to work AO27 and SO35.

Turn to page 26 and follow the instructions for "Custom Tx Offset". Be sure to store away 3 to 4 frequency pairs to accommodate the Doppler shifts.

DopplerShift = Frequency * (SatVelocityInRelationToYou / SpeedOfLight).

Here are the frequency pairs I have programmed up in my FT-50

TX RX
AO-27(1) 145.845 436.805
AO-27(2) 145.850 436.800
AO-27(3) 145.850 436.795
AO-27(4) 145.850 436.790
AO-27(5) 145.855 436.785

SO-35(1) 436.285 145.825
SO-35(2) 436.295 145.825

(Reversed, sometimes they reverse the transponder)
SO-35R(1) 145.950 436.255
SO-35R(2) 145.950 436.250

Message-ID: <38B98995.83FF72E3@localhost.localdomain>
Source record: 63002

I enjoy listening to French radio stations in the north
of England. However, my domestic receiver produces a
slightly noisy signal during the day and is swamped by
other stations at night. A family friend (and radio HAM)
has pointed out the limitations of my radio and the need
to construct a suitably long aerial/good earth.

I would be grateful if someone could point me in the
direction of a quality long wave receiver circuit schematic.
I am capable of building fairly complex circuits as I have
experience in data acquisition/instrument control
and signal handling. I have searched the web but can
only find short wave circuits.

Many thanks

Andy

> they do in empty space far from an antenna.
> . . .

This statement could be interpreted in a couple of ways, and lead to a misunderstanding if the wrong interpretation is chosen.

The equations governing EM fields are the same at any distance from the antenna, including all of the near and far field. In this sense, then, EM fields behave exactly the same in all regions. There's no magic area or distance at which the equations and behavior change.

However, some components of the EM wave change and fade very rapidly with distance from the antenna, so components and characteristics which are significant or even dominant when close to the antenna are for all practical purposes nonexistent at greater distances. This allows simplification of the equations governing EM waves in the far field. The factors important in the near field still apply, but in the far field they're so small they can be ignored with no practical loss in accuracy. So in this sense the behavior of the EM wave is different in the near and far fields as Beaty said.

Date: 2000-02-27 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <89c6mc$83m$1@neptunium.btinternet.com>
Source record: 63007

The internal resistance of a tuned loop is radiation resistance Rr plus conductor loss resistance Rc. This sum has to matched to the receiver input resistance usually 50 ohms.

And so a transformation step-up voltage ratio of Squareroot(50 / (Rr + Rc)) is needed. The losses in the transformation can be made negligible. The efficiency of the antenna is then simply

Efficiency = Rr / (Rr + Rc).

If a loop antenna is near the ground or or other conductors there will be an extra loss. This is taken into account just by increasing Rc.

For the same amount of copper a multi-turn loop is invariably less efficient than a single turn loop. A single turn made of 30mm copper water pipe is the best form of construction unless the frequency is so low you can't find a large enough value of tuning coapacitor. For medium and long wave reception use a box or frame antenna.

Download in a few seconds programs RJELOOP1 and RJELOOP3 from my website below. Not zipped up. Can be run immediately.

I discovered last night that I do in fact have a schematic, though I know I've looked before when Bill has mentioned the receiver. It's in the 1969 edition of the ARRL Handbook (and probably other years).

What's interesting, once you understand how the BFO gets to the detector, is that it's just a simple envelope detector, like you'd see in plenty of receivers before SSB took over. You'd turn on a BFO for code (and SSB as long as you did things right), but if you turned off the BFO there'd still be audio, unlike if it was a product detector. You'd think that by that time they'd make sure a product detector was in place, though I suppose simplicity and the still common use of AM would prohibit it. There is another superhet in that 1969 Handbook, and it also uses a simple diode detector. A few years later, and every receiver in the Handbook would have a product detector, and sometimes no envelope detector.

In some ways, the coupling through the IF amplifier hints at another scheme that was used in the early days of SSB, and in fact is still useable today: front end beat injection.

You'd lightly couple some sort of stable variable frequency oscillator to the antenna jack of a receiver. You'd tune in an SSB signal so it's strong, and then tune the oscillator so it beat with the incoming signal and inject a local carrier. The advantage of this scheme was that you didn't have to modify the receiver if it had no BFO, and if the receiver was unstable, the tone of the resulting audio did not vary. If the injection oscillator was stable enough, once you'd tuned it to the point where it supplied the carrier of the incoming signal, if the receiver drifted it would vary in strength but the beat from the incoming signal and the injection oscillator remained

the same.

Some of those mobile converters often had a BFO operating at a frequency in the broadcast band, to act in this same way.

If you read the text of the Mighty Midget, they tell you to reduce the RF gain when tuning SSB. This was necessary so the BFO was strong enough in reference to the incoming signal. If the ratio of the two signals was wrong, the recovered SSB signal would be distorted or completely unintelligeble.

So long as you were using a simple envelope detector, injecting the BFO in the IF amplifier, or even the front end, helped to get the beat signal strong enough by the time it reached the envelope detector. Of course, dynamic range probably suffered, since you were asking the receiver to amplify not only the incoming signal, but the carrier oscillator.

I think I could put my fingers on the article a lot easier than a lot
of things that I remember but have to dig for.

However, someone has put a cummulative index of Ham Radio up on a webpage.
There are articles that I haven't found, so it may be missing some things,
and it's broken up into categories so you first have to decide where
a given article might be filed, but it's at:

Linkname: ham radio magazine index : 1968 - 1990
URL: http://webhome.idirect.com/~griffith/hrindex.htm

I'm pretty certain that this is the article I'm thinking of:

Switchable bandwidth crystal filter N2DCH 22 Feb 90

The author has had some articles in the various magazines about test
equipment useful to making ladder filters 9and other things) and
a shortwve broadcast receiver (including ladder filters) in Radio
Electronics (or Electronics Now perhaps, depending on the year it
appeared) which is or wsa available as a kit from Dan's Small Parts,
and he also had an article in 73 about making upper and lower sideband
ladder filters, by the simple process of transposing the crystals
and capacitors so the capacitors are in series with the signal path,
and the crystals go to ground.

Chris: Good question. In fact, that was the question that occurred
to me when I first looked at the circuit diagram.

Here is the question I posed back in summer 1998:

Glowbuggers:

There is a Lew McCoy receiver in the April 1966 QST that is really
very tempting. Three 6U8s. Single conversion superhet with a 455 kc
IF. Crystal filter using two FT-243 rocks.

I have most of the needed parts, but before I start melting solder, I
want to make sure I understand the circuit.

The one qustion I have relates to the detector. Its a very simple
solid state diode detector. Two 1N34a's in a voltage doubler
arrangement between the IF amp and the AF amp. Half of one of the
6U8's is used as a BFO at 455 (+/-) kc.

Here's where I'm confused:

Text reads: "There is sufficient bfo signal injection in V3A (IF AMP)
without using a coupling capacitor, so none was used."

The IF amp has a 455 kc transformer can in the plate. Seems to me if
the mixing with the BFO energy was taking place in that stage, the
resulting AF wouldn't make it through the can to the detector and AF
AMP.

Could it be that the mixing takes place in the detector circuit
itself?

Anyone have any experience with this RX?

Thanks,
73 de N2CQR

I got a number of responses, all of which agreed that the mixing took place in the diode detectors. This one is one of the best replies:

Re the phantom injection and how the audio gets through the IF xfmr. The answer is that there isn't any audio present until the signals go through the detector. If you sum two 455 kHz signals whose frequency is
say 1 kHz apart, you still have just two 455 kHz signals, no audio frequency is present. If you do this with a couple of signal generators
and look at the sum on a scope, you will see what looks like an amplitude modulated signal. The envelope of the sum appears to be modulated at the difference frequency (1 KHz in this case). This effect
is produced as the instantaneous values of the two 455 kHz signals alternately reinforce and subtract from each other as their relative phase varies. The diode detector action can be viewed in at least two different ways. One way of looking at it is that it just detects the amplitude modulated waveform you get from summing the two signals. The
other way is that the nonlinear action of the diode results in an output
current which has components resulting from the product of the two signals. This is similar to the action of a mixer. The result of Sin(a) * Sin(b) includes terms of frequency a-b, which will be the frequency difference of the two 455 kHz signals, or in my example 1 KHz. See any trigonometry book for the formulas for Sin(a) * Sin(b).

So all that has to happen is for some of the BFO voltage to get into the
IF amplifier and show up at the detector. It is hard to keep it out without good shielding, especially when an IF amplifier and the BFO share a common envelope, not to mention coupling via common B+ wiring and filament wiring etc.

Interesting stuff. I hope you build one of these. Keep us posted.

Tom Hix is maybe trying to create false rumours to sell tubes??? Well i would hate to use the word never, but the impact of Svetlana going under is minimal. Besides eimac have equivalents to most of their tubes. So who cares, the prices for the tubes are a rip off considering what they make them for, they should be sold for less and not price fix with eimac.

The self capacitance of a single layer solenoid is not releated to the closeness of adjacent turns unless there are very few turns. Only when there are two or three turns does it become significant.

If there are N turns then the resulting end-to-end capacitance due to closeness of winding is the capacitance between two adjacent turns divided by N-1 which is a very small amount. All the bits are in series.

Self-capacitance is a function of overall length and diameter of the coil and practically independent of the number of turns. It can be determined very accurately by searching for the resonant frequency with an antenna analyser using a single turn link around the centre of the coil.

Reg.

>
> Are you suggesting that such antennas are not linear systems?

Not at all. As far as I know, their behavior is totally
covered by Maxwell's equations. It's part of the dynamics
of the nearfield region. The only "nonlinearity" is that the
EM fields do not behave the same in the nearfield region as
they do in empty space far from an antenna.

> > In theory, a tiny loop antenna can behave as if it

> Do you have pointers to such theory?

Not on WWW. Of the papers mentioned at the end of
http://www.amasci.com/tesla/tesceive.html, the C. Bohren
paper and the Paul/Fischer paper go into the details of
the mathematics. (Me, I understand the overall concepts
and the implications, but don't have the math needed to
see any errors they might make.)

> sort of practical configuration?

I haven't seen equations for making practical predictions. For
a lossless resonator antenna, supposedly you can assume that
the capture area of your antenna is a disk of radius 1/6

wavelength or so. For waves moving parallel to the ground, it
would act like a 1/2-disk (I think). The max received power
at 2 wavelenghts distance would be roughly:

500KW*(PI*1/6^2)/2/(4*PI*2^2) = 400 watts

For an antenna with finite Q, it certainly would be lots
lower that 400W. I bet you can light some LEDs or maybe run
a solar cell motor. Also, I think the physical size of the
antenna interacts with the Q required, so a tall tower or a
very wide metal loop would not require as high a Q in order
to "suck in" power. A big square loop made from copper
water pipe would be much better than a tiny ferrite loopstick.
If the e-field is vertical, maybe a tower with a tank circuit
at its base would be best. Expect some RF voltage to appear
on the tower!

I heard a story that a poor farmer who lived downrange from
a big VLF station in Europe discovered that he could run a
heater off of a long wire fence. The station owners tracked
him down because of the changes in the antenna pattern.
They couldn't do anything legally, so they paid to heat his
home in exchange for his removing the offending "receiver."

> Are you proposing that they (loopsticks) might be any different than
> explained in the standard antenna reference books? It seems to me
that
> those explanations predict the performance actually measured for such
> antennas.

Not as far as I know. I have no such books. Do they
calculate the gain for loopsticks with and without a
tuning capacitor? According to the resonant-antenna
explanations, a 6" loopstick acts "small" for a straight
resistive load, but acts "larger" and pulls in more signal
energy if the loopstick is part of a high-Q resonator. This
is not just a matter of impedance matching, since you can
pick the best resistor for both situations, yet the received
power is different.

Hi Andy,
You didn't say what receiver you are presently using for longwave reception. Perhaps the easiest route would be to build an upconverter, from longwave to HF, then purchase a decent tabletop receiver with good filters. Any older hamband-only receiver would probably work, if it had good filters, and an AM demodulator (if you're listening to domestic AM programming.)
It is not simple to build any sort of receiver, if you're interested in having superheterodyne conversion, with decent IF filters.

I thought they were identical parts, but Texas Instrument changed the
part number at one point. W5DA's article in Ham Radio for December 1977
about an up/down filter converter says it was the TL442's old designation
was SN76514.

It's odd how the device never saw common use in ham construction articles.
I know when I read about it years ago, I was interested in getting some
but I sure couldn't find it easily in small quantities.

It's hardly a magical part. It's a double balanced mixer of the same
form as what's now called a "Gilbert Cell Mixer". The advantage of
the SN76514/TL442 over the far more commonly scene MC1496, was that
all the biasing resistors were built in. Of course, that can
be a disadvantage, if what you wanted didn't fit what the TL442
was set up for.

Given the spec sheet, one could theoretically use a 1496 in it's
place, so long as things were configured properly. Or if things
were really right, an NE602 might work. I imagine how much leeway
depends on what the IC is doing in the circuit, and what purpose
the piece of equipment serves.

From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <89dfrg$38i$1@neptunium.btinternet.com>
Source record: 63017

For long waves only, a tuned RF stage, plus tuned detector, plus audio
power amplifier is all that is necessary. The twin-ganged tuned
circuits are more than adequate around 200 KHz.

If noise and interference levels are too high in northern England
there's little which can be done about it in the receiver itself A
large frame aerial, say 1-metre square, forming the first sharply
tuned circuit might be better than a random length outside wire
because of the ability to null out strong unwanted stations such as
Droitwich and some of the noise.

A frame, multi-turn loop aerial can be designed with the help of
program RJELOOP3 which can be downloaded from my website below in a
few seconds.

>distorted or completely unintelligeble.

Michael: I've had to reduce RF gain very often when the SSB signals
are strong. At one point I experimented with a more explicit
capacitive coupling between the BFO and the IF amp, but for some
reason it didin't work out and I went back to Lew's original scheme.

Michael: Thanks. Very interesting. I'll check it out. Seems to go
against the conventional wisdom on filters, i.e., narrow CW filters
are relatively easy but wider filters for phone are much harder.

BTW: I was thinking a bit more about our comparison between my RX in
"wide" mode and a DC receiver with a converter. I think my RX is
really a step or two beyond the converter- DC equivalent. First, we
have the IF amp. This of course allows a better gain distribution and
avoids the heavy dependence on AF amplification that you have in DC
receivers. Then there is the product detector and BFO.

I've been less than thrilled with the DC receivers that I've used
(with the exception of the HW-8's rx!) but I really like my superhet
in the broadband mode. This morning I've been listening to the
W9NS/mm working VKs. Some sort of DX expedition en reoute to exotic
climes.

Receiver madness continues here. I was at a hamfest yesterday and
bought a couple of junky old AM/FM broadcast receivers with "extra"
(police, air, wx) bands. Couldn't resist. At the very least they
will serve as a source of Toko coils and transformers. Also got a
little TenTec SW regen.

As the '50 is not a true dual-band unit, full duplex operation is not
possible...no matter what, if you are transmitting, no receive is
possible.
Some other dual-band radios can do it, unless they mute the receive on the
other band during transmit.
I know, for example that the ICOM IC-W2(probably IC-W2E, for you, here
it's the W2A) can do it.

2235 Hz give or take a few nano Tesla

Quoting from the Proton magnetometer Web
Pagehttp://hometown.aol.com/alka1/ProMag.html

"In the northern latitudes of the U.S. the total magnetic field strength is in the order of 50,000 to 55,000 nanoTesla and varies from location to location. Short period variations due to magnetic storms may reach several hundred nanoTesla. Diurnal variations caused by solar induced ionospheric currents are in the order of tens of nanoTesla. Presently, the long term trend of the total field is in the order of minus 90 nanoTesla per year (steadily decreasing).

The proton precession frequency detected by a suitable sensor in the geomagnetic field of the earth will be at a frequency in the audio range:

Example: 42.58 mHz / Tesla x 52500 x 1E-9 Tesla= 2235 Hz

The"Larmor frequency" defines the angular momentum of protons precessing in the presence of a magnetic field. There are currently quantum-mechanical views that explain particle precession, but a classical explanation seems a bit easier to follow.
A proton, a charged particle, may be thought of as having definite "spin" about an "axis" and acts as a small magnet. An externally applied magnetic field does not alter the spin rate, but causes the particle to wobble at a slower rate about an axis of precession. This axis tends to align with an external magnetic field. However in weak magnetic fields, any alignment tends toward randomness due to thermal effects and other molecular interactions. "

Another comment ....
On the antennas are that any gain in voltage is due to the local storage of the energy from cycle to cycle. The changing electromagnetic field is building up and collapsing about the antenna structure. This being analogous to "q" in a resonant coil.
Antennas have an aperture, effective height -area . The amount of energy a system can absorb depends upon the cross sectional area the antenna and the wavelength of the EMF. It cannot absorb any more energy then is available in the "near zone" of the

antenna structure. In the near zone the permeability and permittivity are not the same as free space.

There is a difference between a resonant magnetic circuit and an antenna.
A resonant coil or magnetic circuit stores the electric and magnetic field from a changing EMF.
An antenna will create EMF plain waves and the energy is radiated away.

In the near zone the antenna stores any absorbed energy.
The near zone or the inductive zone the electric and magnetic field can have phase relationships other then 90 degrees as in electromagnetic waves. Phase velocities in this close area can be superluminal and seemingly exceed the speed of light. This does not violate any of the rules of relativity this just means the energy wave can change its slope. The wave front does not travel at greater then the speed of light no information is passing from point --a to point-- b faster then light.
Any radiation created an antenna is lost to free space and is not stored from cycle to cycle of an oscillating EMF.
Any energy in the far zone does not interact with the antenna until it intersects the antenna- Because of the phase retardation and the electromagnetic wave electric and magnetic field have a 90 degree relationship. (The antenna cannot suck in energy from
the far zone until the energy actually gets to the antenna.) Then the amount of energy absorbed or radiated depends upon the physical dimensions and characteristics dependent upon the wavelength of the EMF.
One could view the amount of energy an antenna can absorb as the same as the amount of sunlight / energy that can pass through an open window. The amount of energy absorbed in any one moment is limited to this effective height or area and the amount of radiation passing through the opening.
If the antenna is part of a larger resonant cavity additional energy could be focused to one area just as a magnifying glass can focus light.

> and far fields as Beaty said.

Right. The nearfield contains static and quasi-static fields,
while the farfield contains only EM waves, yet all of it is
contained under Maxwell.

Part of the reason I'm going on and on about this subject
is that *I* want to achieve a better understanding of this
nearfield stuff. Maxwell's equations describe it all, but they
don't automatically produce visual and verbal models. If
Maxwell's equations are the "bricks," then I want to understand
"architecture." A pair of loop antennas is not the same as
a transformer, and I want a clear understanding of the
difference. Strange things seem to happen when we place a
tuning capacitor across a loop antenna, and I want the strangeness
to be replaced by understanding. Nearfield stuff is muddy for
me, and I want a much clearer visual picture of how RF energy
gets from the wires to the empty space.

Debates about "crossed-field antennas" forced me up against
these very concepts, which helped alot. "Energy-sucking
antennas" is doing the same. Those papers about atoms and
light exposed parts of antenna-physics which I was totally
clueless about. On looking around, I see that I'm not the
only one.

I think it was Richard Feynman who said "if you don't have
three or four different ways of explaining something, then you
don't really understand it." Textbook explanations give one
way, but if we take them as the holy words of Authority,
we'll never encounter all the other ways. Non-traditional

explanations could be dismissed as needless eccentricity. I take the opposite stance: non-traditional explanations give you an alternate set of mental tools, and they fill in the gaps in traditional explanations. If the non-traditional viewpoints haven't been explored to death, maybe there are even some ideas for cool "toys" lurking unsuspected within them.

"Genius in truth means little more than the faculty of perceiving in an unhabitual way."

Rich,

Look into the MFJ 94xx series "travel radios". They're SSB only from the factory, but have an optional CW adaptor. I talked to a station using one the other day, and it sounded great on SSB. I've also had several QSO with them on CW, and they do well there too. I've owned several of the MFJ 90xx CW-only QRP rigs, and they perform well too. The Ten-Tec CW QRP kits are well worth the money, as are the Small Wonder Labs kits (I have three of NN1G's rigs myself right now!).

Back in 1971 when I was 11, I bought a shortwave receiver. It was a Hallicrafters S-120A, pretty expensive for me, but just about the cheapest there was at the time. I've said it in other newsgroups, but it was the world's worst shortwave receiver.

It was lousy for a lot of reasons, but one thing it definitely couldn't do was receive SSB, even though it had a BFO. I can't remember whether I figured out the problem myself, or read something and realized that was the problem. I do recall having the impression that the SSB signals were too strong. Whatever happened, I took a potentiometer I'd taken out of some junk piece of equipment, and used it as an attenuator at the antenna terminal. Suddenly, the receiver did work with SSB. However, by the time I'd attneuated the signals enough for the BFO to work, there were only a handful of signals that made it into the receiver.

The BFO was just not strong enough to properly beat with the incoming signal in the envelope detector. Attenuating the signal made the BFO strong enough.

This was the scheme that was in all the books up until AM receivers started fading away, under the topic of "tuning an SSB signal". Turn off the AGC, turn up the audio gain, reduce the RF gain. Up until SSB became common, receivers never had product detectors, and there was no problem with CW.

As a matter of fact, I was lucky because I went from that S120A to a Hammarlund SP-600, and it didn't have a product detector either, so I had to tune things the same way. But the Super Pro was a great receiver, so it all worked fine.

To fix the problem, one has to go to a product detector. And as already pointed out, that might be a problem in this case because the BFO signal gets coupled into the IF amplifier.

Sure, add more tubes, a bigger power supply, bigger filter caps, bigger diodes, bigger gauge wiring, etc. However, you are better of running it as it is. The difference between 600 watts and 1000 watts amounts to less than 1/2 an "S" Unit...

Now, if you take the money you will save on trying to squeeze a few more watts out of the amp, and work on making your antenna more efficient and lowering feedline losses, you can make a noticeable difference - both in transmitting as well as receiving...

What I was really getting at was that you wouldn't have much selectivity, and definitely not single signal selectivity, once you bypassed the crystal filter. In other aspects, it probably is better than a straight direct conversion receiver, as you point out.

Like the direct conversion receiver, your selectivity with the crystal filter removed comes from the audio response, and the audio image is still there.

Single signal selectivity didn't arrive on the scene until some years after the superhet. I gather a major reason for Armstrong designing the superhet was to move the signal down to a lower frequency where it was easier to get gain back in those days, and putting most of the gain at a fixed frequency simplified things a lot. Sharp selectivity came later.

But that was so long ago, and we are so used to having narrow selectivity in the IF of a superhet, that saying "a direct conversion receiver with a converter" seemed like a way of describing things in a fashion that more could visualize.

There have been receivers described, and I thought Ten Tec even once sold a rig, which could be described as a direct conversion with a converter, or alternately a superhet with no IF selectivity. It just depends on how you look at it.

And of course, there have also been receivers that try to meld both, where they have a sharp filter in the IF, but very little IF gain. They make it up in the audio chain, just like in the direct conversion receiver.

Keep an eye out for CB sets. They have narrower 455KHz ceramic filters
in them than AM broadcast receivers, and so they might be of use to
you.

Source record: 63034

My HF rig is basically incompatible with my keyboard and subwoofer speakers. Pretty much across the entire HF spectrum, I have various amounts of interference with both devices. My keyboard just stops working, all lights and keys become disabled, and my speakers "burp" loudly on voice peaks. I tried puting thick ferrite chokes on both ends of the keyboad to no avail and haven't done any bypass or anything to it or the speakers yet. I was hoping others had been this way before with millions of these things out there and could say, yeah, put a .1uf cap here and a toroid there and it will work just fine. I am only using 50-100 watts, but it still overloads my computer accessories. Thanks.

Hi Gang,

I'd like to build a linear using a 4CX1500b (have tube, socket, plate xfrmr, etc)... What I'm looking for is HELP! Schematics for a solid design using this tube. And any other info that might be helpful. This is my first linear project and I'd like it to not blow up when I plug it in :)

>F 455 Y 21 6419 ï¿½526 9337 00
nominal 2.1kHz @ -6dB, 5.3kHz max @-60dB

All case style Y, cylindrical 2&1/4" long, 7/16" dia typically with a mounting flange, but there was a style with an optional mounting bracket.

Insertion loss ???, maybe somebody else can help

Paul, Here is the url to a page with a one tube regen. It is a pretty crude but neato setup that I am sure you can modify for your needs.>>>http://www.ezlink.com/~crash/parks/1distget.html I believe I would buy commercial parts rather than making the caps and tuner assy,though making everything from scratch could add an element of satisfaction to the project. I bet that the tuner in this plan is a bear to tune satisfactorily.

I have 8 each Ma-Com Model MA-86501 Gunnplexers for sale.

The original specs were as follows:
Center Freq: 10.525GHz
Power Out: 5 to 10 mW Typical
Operating Voltage: 8.5 VDC @120 mA

These have the UG-39 (WR-92) Flange output. I have retuned all
of them to 10.400GHz at 7.5 VDC.

Price is $25 each Plus shipping and handling.

Please e-mail directly to k6ohh@qsl.net

Source record: 62958
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I'm building a microprocessor based auto tuner and need help on
the tuning algorithm.

The tuner is a PI network (2 caps, 1 ind) with individual stepper motors for
both caps and inductor. I have a phase detector that tells me if the load
is too inductive or too capacitive. Also have an SWR detector that starts
the auto tuning process when it detects a high SWR.

Can anyone point me in the right direction to solve the tuning algorithm.
For example if the phase detector tells me that the load is too capacitive,
which cap should I rotate???

Can anyone tell me what "false" tuning points are?

>
> That would require a current source composed of a dynamic, nonlinear,
> resistance.

Not exactly. We were talking about a carbon sheet with a
power supply connected across two edges. If I place two
small electrodes at the center of the sheet, and then connect
a big capacitor to them, what will occur? At first the
capacitor will act like a dead short, since the voltage across
the capacitor starts out at zero during the first instant.
There will be a relatively constant capacitor current because
of the carbon resistor, and because the voltage of the capacitor
is so tiny compared to the power supply that drives the sheet.
No fancy constant-current supply is needed, we just need a
power supply and a resistor.

As the capacitor voltage rises, the current through it DOES
NOT fall much, since the voltage across the capacitor is still
so small. For small capacitor voltage, the energy flowing
into the capacitor is roughly proportional to voltage. It's
this way because the capacitor voltage is rising, but the
current through it is only falling a tiny bit. Under
these conditions, if we wanted to force the capacitor to
gather energy at a faster rate, we could goose up its
voltage artificially. Within limits, the higher the
capacitor voltage, the greater the energy flow going
into it.

> > then you're pumping in a millijoule of energy per
> > second into the capacitor.
>
> The current source to charge that capacitor might have used 1 volt,
but you
> failed to spec the capacitor which I must assume was constant, as
E=1/2

Yes, the C is constant.

> CV^2. Now if C is constant, and the voltage is constant, the energy is
> constant too.

Definitely not. When a capacitor is being charged with a
power supply and a resistor in series, the capacitor voltage is
not constant, yet the capacitor current is almost constant.
Energy flow into the capacitor starts at zero (because the
capacitor voltage starts at zero, and energy flow is V x I.)
Then the energy flow rate rises because the voltage rises MORE
than the current falls (look at P = V x I.) Then the energy
flow into the capacitor reaches a peak and starts
falling. Eventually it decreases to zero again because
the capacitor voltage has settled at a maximum value, and
the current is zero. If you don't believe this, plug it
into a spreadsheet or a CAD program. Calculate the V x I for
the capacitor, and you'll see the incoming power rise, peak,
and fall.

This is all an analogy for the "energy sucking antenna", but I
think it's a good one. Something similar should occur when
a lossless resonator is first illuminated with EM waves:
at first the energy flows in fast, then there is a peak in
the flow, then the flow tails off as the resonator settles down
to a constant high value of internal energy.

The important part is right at the beginning, because the amount
of energy flowing into the resonator depends on the intensity of
the resonator's fields. The stronger the fields, the greater
the intercepted power. It's analogous to the early stages of
the charging capacitor: the greater the voltage, the greater
the energy flowing in.

> > But if you let the voltage across
> > the capacitor rise to 2 volts, then you're pumping in 2mJ
> > per second.
>
> You must be talking about a capacitor that is dynamicaly changing
> capacitance,

Nope. ALL capacitors do this. (However, I certainly
never encountered this concept in engineering school. I never
sat down and plotted the energy flow of a charging capacitor.
Heh. Back then I wasn't totally away that "power" meant
"energy flow rate.")

> that is nonlinear, because you keep a constant voltage across a
> capacitor as you increase the stored energy at a linear rate.

When an "empty" capacitor is first connected to a supply with
a resistor in series, the voltage goes up but the current does
not go down in proportion, therefore the amount of energy per
second flowing into the capacitor goes up. Another way to say

it: the higher the voltage across the capacitor, the faster
the energy comes in. (This only holds true until the
capacitor voltage becomes significant relative to the power
supply voltage.)

>
> > In the case of small resonant

>
> Now we're talking about a different situation, with an LC and
sinusoid.

Yes, different. The capacitor is only an analogy. But
not so different that the analogy evaporates.

The
> LC will 'ring up', initialy presenting a greater load to a source
delivering
> a constant voltage. Now I see what you mean, I think. You mean that
the
> power extracted from the incident field is dependant on the energy in
the LC
> tank.

Exactly. However, in the case of the antenna, we have some
three-dimensional field patterns, so it doesn't behave exactly
like a signal generator connected to a tank circuit through
a resistor. With direct wire connections, the ratio between
the voltage of the signal generator and the voltage of the
tank circuit is the determining factor. With an antenna, the
SHAPE of the fields (their broadside area, to be specific)
becomes important too.

> Considering a sinusoidal field potential, and a sinusoidal tank
> voltage of equal value, there be no energy or complete energy
extracted
> depending on relative phases, of 0 or 180 degrees respectively. OK.

It also depends on the amplitude of the current in the loop
antenna (or, if its a short dipole, it depends on the voltage
across it.) If the resonator hasn't "rung up" yet, then it is
not yet generating its own fields, therefor the incoming EM
waves are unaffected, and they pass right by it without
being absorbed. To be absorbed, they have to flow TOWARDS
the body of the resonator and not just flow along undeflected.
Only when the strong fields of the resonator are superimposed
with the fields of the incoming EM waves do we have energy
flowing INTO the tiny resonator.

Yes, all this is very weird. It's like putting a bucket out
in the rain, and discovering that a full bucket gathers more
rain than an empty one!

>
> This has nothing to do with "concentrating the Poynting vector

think
> what happens with atoms and photons is a changing of the properties
of the
> vacuum, a warping of space-time for the EM poynting vector and
dynamic E and
> B fields.

If the e-fields and b-fields of the tiny resonant antenna are
the reason that EM waves flow into that antenna, then no
spacetime warping is needed. And, if no spacetime warping is
needed for small resonant antennas, it *MIGHT* be true
that individual atoms use similar physics.

> > This occurs naturally in a resonant

>
> I don't think so. If you don't criticaly damp, that is conjugate
match,
> absorb all the energy from the LC antenna, it
> will not cancel the field as you think.

You are right. The "lossless resonant antenna" requires a
load, otherwise it will become "full" and will stop absorbing
energy. However, the load resistor has unexpected effects.

Here's ANOTHER way to look at it. Suppose we have a simple
loop antenna (electrically small, not resonant.) Suppose
we illuminate it with EM waves. We can put a variable
resistor across it and adjust the resistor for maximum
received power. Matching the load impedance, obviously.
OK, now put a capacitor across that loop antenna and tune
it to resonance with the incoming waves. Finally, adjust
the load resistor to achive maximum power. You'll find
something very strange: the resistor value is very different
than with the non-resonant antenna (I mean WAY different), and
also the received power is much, much higher. This is not
just an example of impedance matching, since the resistor
in both cases was adjusted to match the antenna impedance.
Adding the capacitor did something odd. It increased the
antenna's coupling to space, as if the antenna had become

larger.

> If you let it ring up to the
> incident field potential and cease to absorb power. How do you get a
180
> degree phase shift field without constantly supplying the energy to
do it,
> and then radiating away that energy? It sounds like your talking about
> active signal cancellation. What wonderfull stealth that trick would
make!

Right! As far as I know, it really works this way: an array
of tiny antennas can act as an absorber-sheet, even though there
are huge empty spaces between the antennas. The stored energy
in the resonator makes the antenna behave like an actively-
driven device. (Unfortunately its a narrow-band phenomenon.)

>

it in
> the potential energy of its orbit (or resonance).

Yep. The "resonant antenna" idea comes into play if we can
cause that electron to "slosh" much farther from the nucleus
than usual. When its close to the nucleus, its field is
partially canceled, but if we can give it some resonant
pumping, its field can expand out into space far from the atom,
and that means its field can interact better with EM waves.
That's the "energy sucking antenna" phenomenon in action.

Of course it would be best to just get rid of the positive
nucleus and let the waves hit the electron directly. An
antenna composed of uncancelled electrons would be REALLY
effective. But if the darned electrons insist on staying
near protons, then the next best thing we can do is to
get them "swinging", so they spend as much time as possible
lifted far outwards away from the protons, so the EM waves
can "see" them.

Doesn't this require some modification to Maxwell's equations?

Nikola Tesla claimed to have achived a "bubble" effect which
could apply forces against solid matter. If he really did
this, then maybe the effect can be demonstrated with
desktop equipment, if we knew the right combinations of
coils, plates, and drive waveforms. Maybe there is a "standing
wave" version of your EM solitons. In particular, if one EM
soliton can reflect off of another, it might be possible to
generate a sphere-shaped structure made of soliton-stuff, where
the shell of the sphere keeps the solitons bouncing around
inside. If atoms are these, except with high frequency and
smaller size, then maybe it's possible to generate a stable
"VHF atom" which is many inches in diameter? Star Trek
technology, obviously!

 Using less power than is needed to communicate comfortably is clearly a torment to others. // One summer evening on 75m, a QRP proponent broke into our SSB-VOX group. Within the first minute he launched into a painfully long Lock to Talk diatribe about the evils of high power. We switched to USB and continued as before while he blathered away on lower. If it turns out that there is a place called Hell, it seems quite likely that it will be inhabited by those who found comfort in the torment of others..

I would use a G3SEK tetrode board, this board will give your tetrode good protection. It is available in the USA. It has screen and grid regulators plus numerous protection measures. A good product overall, although there is some messing about when you want to use different screen voltages, pity they did not specify all the component values for all the popular tubes. My only criticism for this board which is sold as a complete sollution.

Source record: 62963

I have a Kenwood TS-850SAT and this radio have a "oscillateing" output. In FM it is wery obvious but i have also seen it on RTTY. At 50 Watts output FM does the output goes from one white dot below where the read dots start to one read in the meter. It is also visibel on a external meter and on the current drain from my power. The power drain from the power supply is not to high. It is normal and it not too much to handel for the powersupply either. I do hope that someone on the list may give me an idea of what the trouble may be.

Please answer me of the list at la5hja@repairman.com

Rich, I certainly share your disdain of rude operators, including this QRP op.

But I would not want newcomers to think that yours is the majority view about receiving QRP. Throughout my years of operating in the 50-100 w output range, I have gained particular pleasure in the challenge of copying somebody who had the "audacity" to call me with their 1 watt rig. I qso'ed someone the other day running 500 mW from 1200 miles away, for over 30 minutes on 40 meters. That was just plain fun! Granted, it won't be fun for everybody, but then there's nothing in the FCC rules or amateur code that says you have to answer a call from an s3 signal. Still, if all you want is armchair copy, you're excluding an awful lot of grassroots ham radio activity. Your loss...

1565. impedance w/scope

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-01 00:00:00 UTC
From: Paul Martin <pmartin@bright.net>
Message-ID: <38BD4460.D2C63363@bright.net>
Source record: 62970

Am I correct in my analogy? I have a circuit succeeding an NE602 mixer but I am not sure it presents the proper impedance to the 602 (1500 ohms). If I watch the output of the 602 with a scope and shunt a variable resistance across it until I see half the original p-p waveform then that resistance value should be approx.the impedance across the output.

The reason I want to check this is I have a mixer that appears to be working okay but the output is down. The input is -20db which is the compression point of the 602 and the output is barely above that but the rated gain of the 602 is supposed to be14 to 17db. Looking at the schematic of a 602 I don't really see how if it has a bad transistor I am getting good mixing characteristics. Gain and mixing should go hand in hand with the 602 so I am left wondering about proper impedance termination.
Any thoughts?

True Hannes, but C1 L1 are the major frequency determining components,
so the formula will give a figure which is near enough to be able to
trim by removing a few turns, or adjusting the coil core.

>Can anyone point me in the right direction to solve the tuning
>algorithm. For example if the phase detector tells me that the load is
>too capacitive, which cap should I rotate???

>Can anyone tell me what "false" tuning points are?

>-rob N7QT

What is the "source" for the RF? Will there be two "tuners" used, one in the transmitter and one in the feedline, perhaps at the antenna?

In the really old days we would tune for max RF current in the line.

(In the not quite so old days we monitored the final plate current and tuned for a dip, but that was when radios glowed in the dark)

In the old days the setting of the series "L" arm is determined by the band.

You start with the output "loading" capacitor fully meshed.

You now adjust the input "tuning" capacitor for maximum line current.

Increase the loading, by reducing the output "loading" capacitance in small increments, while simultaneously maintaining the maximum line current by adjusting the input "tuning" capacitor.

At some point, further loading adjustments will not increase the line current. This indicates some combination of the maximum coupling range of the PI network and/or the maximum power output of the RF source.

If you use a modern auto-tune transmitter I would suggest you first adjust it for rated output into a 50+j0 ohm dummy load.

Now turn off the auto tune feature, connect the PI+feedline+antenna, and see if the PI network adjustment described above can transform the actual load "seen" at the shack end of the feedline into something close to 50+j0 ohm's that the transmitter is tuned for.

After the "best" match is achieved from the PI, the auto-tune of the rig can once more be enabled with perhaps a wee-bit more output power.

Using proper components to build the PI network and selecting the optimum length of the feedline (determined by the actual antenna characteristics) you should be able to load almost anything from a beam to a flag pole.

>I have a phase detector that tells me if the load is too inductive or
>too capacitive. Also have an SWR detector that starts the auto tuning
>process when it detects a high SWR.

Taken out of context and by themselves there is no such thing as "too much reactance" nor is there "too high" a SWR.

Any antenna+feedline will result in a complex impedance and SWR (as "seen" by the transmitter) that can be "calculated" with reasonable ease. Unless your calculations are wrong or the physical plant is defective (broken wire, bad solder joint, calculating in meters and measuring in feet) then only if the complex impedance at the shack end of the feedline is beyond what the "tuner" can handle is there too much reactance, too high/low a resistance.

This is a deficiency of the tuner.

This deficiency can be compensated for by adjusting feedline length. (in most cases) See the "all band" system that Cecil uses as an example.

One solution is to turn your pi into an 'L' with the cap being switched
from input to output as needed. This greatly simplifies the tuning
algorithm.

The easiest way is to look for 'communication specialists' modules;
HRO sells these. They are itty bitty modules, small enough to put
in nearly all equipment (I have an en/decoder that is the size of a
postage stamp).

As to chips, Consumer Microsystems Limited (CML, http://www.cmlmicro.co.uk/)
is about the only game in town. The easiest way was the FX365 , but that
is being phased out; the newer chips are much nicer but probably
need a microcontroller to drive them.
The bad news about CML is that their distribution mechanism is really bad:
because they mainly sell to specialized users, getting these chips
in small quantities is a real pain.

A third possibility is a square wave generator with a stiff low-pass
filter (such as an MF6 or thereabouts). Since square waves only have
odd harmonics, filtering is not hard.

A fourth possibility is using a twisted-ring counter with weighted
resistors to build a D/A converted that generates sine waves;
see page 667 of 'the art of electronics' (if you don't know the book,
purchase one!)

A fifth possibility is what I am currently experimenting with
for a repeater, using a one-bit output from an EPROM and average
the bit stream. Basically, I read out an EPROM at 250 KHz and
use a simple RC filter to average out the ones and zeroes
into a sine wave. The advantage is that it's all-digital
(no critical resistors, no pots), the frequency is crystal controlled,
and the distortion is _very_ low. I get the tones for ID etc for free
and use the EPROM to supply signals for a switched capacitor
filter for CTCSS decode.

The easiest way is to look for 'communication specialists' modules;
HRO sells these. They are itty bitty modules, small enough to put
in nearly all equipment (I have an en/decoder that is the size of a
postage stamp).

As to chips, Consumer Microsystems Limited (CML, http://www.cmlmicro.co.uk/)
is about the only game in town. The easiest way was the FX365 , but that
is being phased out; the newer chips are much nicer but probably
need a microcontroller to drive them.

Anyone got any information on building a fractal beam, quad etc for 2
metres?
What are the basic rules? can they be directly scaled ie. from 10 metres
to 2 metres?
Have you a sure fire design or operation tips?
Apart from a load of bent wire what do I need?

Please help if you can....thanks ... Dave

1582. Help - Need Homebrew Keyer Article

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-02 00:00:00 UTC
From: fretman_2@my-deja.com
Message-ID: <89lv6i$je2$1@nnrp1.deja.com>
Source record: 62898

I'm trying to locate an article that appeared in CQ Magazine in the early to mid 90's. The article was about constructing an electronic keyer. The keyer had two PC board paddles. One paddle was for the dits and the other, when touched, formed a continuous dah. The length of the dah depended on how long the dah pad was touched. The keyer had a pcboard pad on the bottom where the hand rested. When the hand touched the pad on the keyer and the fingers touched one of the paddles the circuite was closed (the hand was part of the circuit at that point) and the keyer activated. I built two of these things and loved the way they worked. I gave them both away and now I'd like to build another but have lost the article.

Can anyone help with a copy of the article???

Thanks and 73!

Icom 781 HF rig with built in tuner,built in scope,built in power
supply. 150Watts, Does full
power, I put it on a dummy load and it puts out 150 Watts. Comes
with Manual,Power Cord.
No original box and no mic comes with it. This rig works 100
percent
and the scope is nice and bright. The metal cabinet that goes around
it has a few touch ups on it.
The serial number is: 01779 As I stated, everything works
GREAT. Of course this would be double boxed
and packed well.

WAS: 2,675.00 NOW: 2,500.00 FIRM
Or trade for GM300 VHF and UHF Mobiles
of equal value or Spectra Mobiles VHF and UHF. Ham Gear,
Also looking for Collins Gear. Just let me know what you have.
Reply Email.
Thanks for reading,Rich.

> which cap should I rotate???

First of all, it should be noted that that the PI network doesn't have a unique tuning solution. You have three controllable tuning parameters and you only need two, assuming all three elements can be varied from zero to infinity. In the case of RF amplifier tank circuits, the additional degree of freedom is used to select the operating Q, (approx 10 usually) but your implementation is free to choose the third constraint based on other criteria more useful for the specific situation such as:

- Maximum bandwidth - probably not an issue for an autotuner unless you are dealing with very high bandwidth signals or unusually high Q antenna systems.

- Minimum loss - Probably nearly the same as maximum bandwidth.

- Avoidance of coil self resonances.

- Algorithm simplicity - This would be my choice. Details of course depend on the components used and the required matching range.

My recommendation is to forget worrying about the tuning algorithm for a while and spend some time determining the system requirements in terms of load impedance range (reactance and resistance), for each of the required operating frequency ranges. You will need to characterize the candidate tuning components over the relevant frequency ranges and estimate the controllability (step size, backlash etc.). You will also need to know in some detail what the 'phase' and 'SWR' detector are actually measuring and over what dynamic range they are useful.

Once you know your requirements and device characteristics you can mathematically determine if it is possible to meet your requirements.

Since this problem is essentially two dimensional, I strongly suggest graphing the solutions parametrically on a Smith chart. Other presentations are useful as well, but a thorough understanding of the Smith chart itself will almost certainly prove useful before you are done. Begin by plotting solution curves using a single inductor and capacitor in each (different colors are useful) of the possible four L network configurations. You will probably find you don't actually require the full flexibility of the PI network and may choose to use a single L and C and a couple of relays instead. If not,
consider an algorithm where either the input OR output C is set to minimum depending on gross magnitude of the transformation ratio. Note from a phase and SWR measurement alone you can not determine which case is appropriate.

Gotta go....

Well, my son and I finished assembling it last night and got it working. I found out that it works much better if you switch the antenna from the ground position over to the 40-m dipole (hi hi). We got a strong signal from the BBC. I assume it's the one closest to 40 m since we're using the coils for the 40 m band.

I'm still going to have my Elmer look at it and help me figure out just what frequencies it can listen to. But it pretty much worked on the first try (see the antenna comment, above) so we're pretty excited.

Drew OM,
Why do you NOT want PIC-based? I've been using an SMT "TICK" (it is
actually an SMT SO8 packaged PIC processor) keyer chip sold by Embedded
Research for a couple of years now for mobile. It is a nice little
chip, and runs for a year on a 3V disc battery. I glued mine to the
bottom of my bencher paddle. Makes a very compact self-contained keyer,
and is programmable from the key too.

...

Linearity, to me, means that the response of a system (the antenna) to one input (signal) is independent of its response to any other signals. That immediately tells me that the response to some signal we wish to receive will not be changed by some other field around, or current in, or voltage across the feedpoint of, our antenna.

Do I get to pick? If I do, I'll opt for linearity.

Cheers,
Tom

Cross-posted to: aus.radio.amateur.misc,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hello,
I would like to have info regarding any dealings that my fellow amateurs may have had regarding Ted Seely, AA4GM as I had some bad dealings with him regarding a deal on Yahoo Auctions for a pair of Heathkit twins. I won them fair and square, but apparently once he found that I am JUST a No-Code Tech class amateur (he being Amateur Extra) decided to not answer my emails in reply to his emails to confirm the winning bid.
My query resides in the above dealings in that I wish to know if this Amateur is renowned for this type of dealing with other subordinate hams. I thought this was a fraternity of learning and mentoring of younger hams by Elmer's who would encourage, but I think that this man overlooks the elmering he once had and the gleam in a budding amateurs eyes at the glowing of vacuum tubes that reminded him of the day when he himself was 13 and an uncle gave him his Heathkit twins to remember him by and possibly become an amateur and subsequently passing this to his children or family members some fine day in his old age. Please if you have ANY such info please contact me that I may warn some of my young amateur friends to STAY AWAY from this man.
I'll step down from my soap box now a bit more educated and CAUTIOUS of my fellow hams as I have been bitten.

: Can any body please tell me how to make a ctcss encoder or give me the chip
: numbers to build one.
: Stewart

Hi Stewart,

A sub tone encoder is pretty easy to make. The best chip for doing an inexpensive single frequency encoder is a 555 timer chip. It has more than enough power to drive a three section low pass filter in the astable mode.

I've been using it for years in one radio. If you email me direct, i'll see if I can dig up the diagram for you. You could even put a knob on the frequency adjustment pot and make it variable if you like.

cheers
skipp

: Bill

Hi Bill,

Everything has gone computer now, not much in the old type original cor/cos timer circuits are around in kit form. The ARRL Handbook would be a great place to start. Another place is Hamtronics... See if you can dig up one of their old COR 2, 3 or 4 circuits. It's just what your looking for.

cheers

: etc)... What I'm looking for is HELP! Schematics for a solid design using
: this tube. And any other info that might be helpful. This is my first linear
: project and I'd like it to not blow up when I plug it in :)

You can find a 4cx1000 amplifier or two on my http://sonic.ucdavis.edu
pages. It's the same basic tube as your 1500b.

[snip]
:I would use a G3SEK tetrode board, this board will give your tetrode good
:protection. It is available in the USA. It has screen and grid regulators
:plus numerous protection measures. A good product overall, although there
:is some messing about when you want to use different screen voltages,
:pity they did not specify all the component values for all the popular
:tubes. My only criticism for this board which is sold as a complete
:sollution.

The board is a nice way for a newbie builder to properly set up a tetrode
with less mistakes, but it's not the only thing out there. Older ARRL
Handbooks are also very helpful.
You should be into building it yourself to learn something. Half the
battle is the homework.

cheers
skipp

ps the tube will really put out a nice signal in SSB AB1 operation.

1602. Re: Simple broadening of CW receiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-02 00:00:00 UTC
From: NANCY GIANAKOPOULOS <n.gianakopoulos@worldnet.att.net>
Message-ID: <r5lv4.4527$NO6.355400@bgtnsc06-news.ops.worldnet.att.net>
Source record: 62988

A good Toko transformer to use at 455KHz IFs is the RMC502-182 transformer; this unit has a center-tapped primary, which makes it good for use with MC-1350 chips. Also, this transformer is great, when it is used with an NE-602 as a product detector.
The Digi-Key part number is TK1305-ND; cost is about $1.75 in small quantities. If you do use this device as the tuned element in a product detector, a BB-509 varactor is a good bet. This diode has a range of 4 to 33pF, with a tuning voltage of 30V to 4V. With a tune voltage of 8 volts, a 10K linear pot, with a 24K resistor at the hot end, and a 24K resistor at the cold end of the pot to ground gives a plus or minus 3KHz tuning range of the BFO. On a final note, the ceramic filters that our Canadian friend is talking about are Murata CFU-455H, of CFWS-455H filters. These filters have a 6KHz bandwidth. The CFU series are 4 elements, while the CFWS series are 6 elements. The bandwidth is specified by the letter code; the E and F bandwidths are for NBFM, the G bandwidth is 8KHz, the H bandwidth is 6KHz, the I bandwidth is 4KHz, and the K bandwidth is for SSB use. Look inside of your Icom, Kenwood, and Yaesu receivers, and you will see the CFWS-455H for AM wide, and the CFWS-455I for AM narrow.
Thanks to everyone who takes the time to read this post!

How to turn $6 into $50,000!-Or more!!-It 100% works!!!
READING THIS COULD CHANGE YOUR LIFE:

This really does work if you give it a honest try!

I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I though, "Yeah right, this must be a scam", but like most of us, I was curious, so I kept reading.
Anyway, it said that you send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured: "what have I got to lose except 6 stamps and $6.00, right?" Then I invested the measly $6.00.
Well, GUESS WHAT!!... Within 7 days, I started getting money in the mail! I was
Shocked ! I figured it would end soon, but the money just kept coming in. In my first
week , I made about $25.00. By the end of the second week I had made a total of over
$1,000.00! In the third week I had over $10,000.00 and it's still growing. This is now
my fourth week and I have made a total of just over $42,000.00 and it's still coming in
rapidly.
It's certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it.

I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!

Suggestion: Read this entire message carefully! (print it out or download it). Follow the simple directions and watch the money come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage)

IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends.

PLEASE NOTE:
Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.
Here are the 3 easy steps to success:
STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." "Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery).
Next, place one paper in each of the 6 envelopes and seal them, MAKE SURE THAT THERE ARE ENOUGH STAMPS ON YOUR ENVELOPES. You should now have 6 sealed envelops, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill.
What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL!
You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal!

Mail the 6 envelopes to the following addresses:

#1) William Rosser - 254 Getzville Rd. Amherst, NY 14226
#2) Rae Patterson - 150 Hauli St. #150 Wailuku, HI 96793
#3)Connie Wrenn - 111 Chesterfield Dr. Elizabeth City, NC 27909
#4)Christopher Petersen - 222 Haulani St. Pukalani, HI 96768
#5) GERALD R. DE CROCE- 2 HERITAGE CT. MORRIS PLAINS,NJ 07950
#6) Alex Beltran - 6650 Hogan Dr., Sacramento, CA 95822

STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc.) and add YOUR Name as number 6 on the list.
STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups or emails, (I think there are close to 50,000 groups) All you

need is 200, but remember, the more you post, the more money you make!
**EVERYBODY AROUND THE WORLD CAN DO IT, BUT REMEMBER TO PUT
ENOUGH STAMPS ON YOUR ENVELOPES!!!!!**

This is perfectly legal! If you have any doubts, refer to Title 18 sec.
1302 -&- 1341 of
the Postal lottery laws. Keep a copy of these steps for yourself and,
whenever you
need money, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the
honesty and integrity of the participants and by their carefully adhering to
the directions. Look at it this way. If you are of integrity, the program
will continue and the money that so many others have received will come your
way.
NOTE: You may want to retain very name and address sent to you, either
on a
computer or hard copy and keep the notes people send you. This VERIFIES that
you
are truly providing a service. (Also, it might be a good idea to wrap the $1
bill in dark
paper to reduce the risk of mail theft.) So, as each post is downloaded and
the
directions carefully followed, six members will be reimbursed for their
participation as a
List Developer with one dollar each.
Your name will move up the list geometrically so that when your name
reaches
the #1 position you will be receiving thousands of dollar is CASH!!! What an
opportunity for only $6.00 ($1.00 for each of the first six people listed
above). Send it
now, add your own name to the list and you're in business!

--------DIRECTIONS--------FOR HOW TO POST TO NEWSGROUPS--------------
Step 1) You do not need to retype this entire letter to do your own
posting. Simply put your cursor at the beginning of this letter and drag
your cursor to the bottom of this document, and select 'copy' from the edit
menu. This will copy the entire letter into the computer's memory.
Step 2) Open a blank 'notepad' file and place your cursor at the top
of the blank page. From the 'edit' menu select 'paste.' This will paste a
copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do
your postings in different settings, you'll always have this file to go back
to.
Step 4) Use Netscape or Internet explorer and try searching for
various newsgroups (online forums, message boards, chat sites, discussions).
Step 5) Visit these message boards and post this article as a new
message by
highlighting the text of this letter and selecting paste from the edit menu.
Fill in the
Subject, this will be the header that everyone sees as they scroll through

the list of
postings in a particular group, click the post message button. You're done with your
first one!
Congratulations THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!

**REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!!

BUT YOU HAVE TO POST A MINIMUM OF 200**
That's it! You will begin receiving money from around the world within days! You may
eventually want to rent a P.O. Box due to the large amounts of mail you will receive.

----------Now the WHY part----------
Out of 200 postings, say I receive only 5 replies (a very low example).
So then I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00!
Now, those 125 persons turn around and post the MINIMUM 200 with my name at #3 and only receive 5 replies each, I will make an additional $625.00!
OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at #2 and they each only receive 5 replies, that just made me $3,125.00!!!! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625.00! With an original investment of only $6.00!
AMAZING!
When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is: do you realize that thousands of people all over the world are joining the Internet and reading these articles everyday? JUST LIKE YOU are now!!

So, can you afford $6.00 and see if it really works?? I think so

Remember, play FAIRLY and HONESTLY and this will really work.
GOOD LUCK!!!!!!!!!!!

...and here we have the supplier's dilemma: one customer wants all the details worked out for him, while someone else wants a challenge!

I've tried to meet both needs.

On the one hand, I supply every set of boards with a comprehensive manual that step-by-step commissioning instructions. There cannot be a single set of component values that fits all tubes, so I give guidelines for changing the voltage and current ranges. There's also a more extensive Application Note on the web site. If anyone needs more specific help, I'm only an e-mail away.

On the other hand, my web site contains a downloadable article that explains all the background - and shows why you should *avoid* some screen supply ideas from older ARRL Handbooks! The article also gives schematics that many people have used successfully without needing the ready-made boards.

I had the same problem and here's what worked for me:

1. If possible, get a keyboard made by Maxi-Switch. I have used two
different models, one standard and one programmable, and they were both
totally rf-proof, even at the 1500 watt level, whereas other makes of
keyboards were trashed by as little as 50 watts of rf.
2. Before I did #1 above, I was using a 40-meter inverted vee fed directly
with coax (no balun). Installing a choke-type balun at the feedpoint of the
vee reduced rfi greatly.
3. Get the ARRL book on rfi. Lots of good ideas there.

Hi Paul,
Just in case Alan doesn't get back to you,
if you have a X10 scope probe with 15pf of capacitance
that is equal to 213 ohms of impedance at 50 Mhz. That
will load your circuit.

The LM337 will not mind the 1V RMS in its control leg. What you have to aviod is adding any DC resistance in the control leg. It will cause the DC output voltage to increase. A transformer will allow you to couple in the sinewave without adding DC resistence. Or if there already is a resistor in the control leg leave it there and use a capacitor to couple in the sinewave.

I came across 4 Switching type power supplies rated at 15v 150 Amp each. Trouble is the power input to them is 3 phase. The input is a three phase rectifier and filter. The filter caps are a couple of big computer grade jobs rated at 200VDC. Looks like this should develope about 150VDC to supply to the inverter section of the power supply. I want to run this off of single phase power, any suggestions on how to do this would be appreciated. I was considering buiding an external 150vdc supply and connecting it to all three phases.

1620. WIFB Article on QRP Transmitters and 2N2222's

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-03 00:00:00 UTC
From: Curtis Scholl <cscholl@izzy.net>
Message-ID: <ucPv4.720$D7.13383@news.itd.umich.edu>
Source record: 62924

Hello group!

I hope I can get someone with back issues of QST to help here. Around 80/81 W1FB, Doug DeMaw, wrote some QRP Xmitter articles with schematics. The particular article I am looking for was a revisit and modification of an earlier project related article. I had a copy of the article and have misplaced/lost it.

The article describes the modification of the final amp of a QRP transmiter by adding transistors in parallel and driving them to produce more power. There were 4 transistors in the final and they were 2N2222. The transistors were epoxied to the cobbled up heat sink of PC board. He used ferrite beads on the leads of the transistors to keep from radiating at VHF.

This is all of the description I have. I do not know the particular frequency/band that the article project was for. I would like to get this article for potential modification of my RAMSEY qrp rigs. I did order the 30 meter version of the QRP rig and the 30 Meter version of the linear amp.

I also have the 20 meter unit. Modifying them would be interesting.

Thanks in advance

Curtis Scholl

>or voltage across the feedpoint of, our antenna.

Linearity => An operation is linear if op(aX + bY) = a*op(X) + b*op(Y)
a,b complex, X,Y functions

multiplication by a scalar is linear, squaring is not, etc...

The HP 200CD oscillator is an example of a valve audio generator. There are also Heath valve audio generators along the same lines. I might be able to send you a .gif of one or the other if you can't find it locally. The HP design is a classic, and may well be on a website somewhere. It's the design that got Bill and Dave started in business over 60 years ago.

Cheers,
Tom

Hmmm, real low QRP. 2N2222 are GP NPN devices for switching, osc, amps,
etc. but no real power. They undoubtedly were the metal case versions.
Moto has plastic equiv MPS2222. I'm sure there's a slew of other
similar
devices.

Just a heads up that the Feb 21 2000 Electronic Design magazine has a design idea from Mr. Paul Woods on a DTMF/CTCSS decoding circuit for older radios where this feature isn't present. I know I'd looked for this once upon a time and DTMF decoding often comes up as a topic here.. URL follows:

http://www.elecdesign.com/magazine/2000/feb2100/ifd/0221ifd1.shtml

1633. signal generator vs. waveform generator?

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-03 00:00:00 UTC
From: gagnon@gagnon.fakeu-net.com
Message-ID: <38c00cf8.613613@news.u-net.com>
Source record: 62937

What is the difference between a signal generator and a waveform generator? If a waveform generator can output a sine waves at HF could it not be used as an RF signal generator?

Sure. Usually a waveform or "function" generator tunes lower in
frequency than a "signal" generator. Most go down to a fraction of a
Hz, and up to a MHz or two.

A signal generator usually stops at a few hundred kHz on the low end,
and goes up through whatever MHz or GHz it's rated for. They're more
likely to have high-quality, calibrated RF attenuators, while a function
generator's attenuator usually consists of an uncalibrated or
relative-reading pot. Frequency calibration and high-frequency
stability is likely to be better in a "signal generator" than a
"waveform generator," although that's not necessarily true of newer
digital models.

Most RF signal generators are designed for sine-wave output only.
Waveform/function generators put out a variety of waveforms (sine,
triangle, sawtooth, square...) and often allow the user to vary the DC
offset and duty cycle of the waveform. These functions are seldom
needed in RF work, but it doesn't hurt to have them as long as you can
still get a relatively-clean sine wave from the instrument.

Source record: 62941

The short answer is sure, if it outputs sinewaves at HF it could be used as an RF (HF) signal generator. But you might very soon realize there's more to it than just that. I'd want to ask some application oriented questions:

Do you need the ability to generate arbitrary waveforms, or will you always want a single carrier frequency at a time (perhaps with modulation)? Is the generator capable of accurate modulation of the types you need? What of frequency settability, accuracy and stability? Are spurious outputs (both noise and discrete frequencies) sufficiently low in amplitude? Does it have accurate output signal levels, covering the desired range? Is the user interface what you want? If you are happy with answers to those questions, then you've probably found what you want. So I think the real answer lies deeper than just the method used to generate the carrier. For what you're doing, a very simple fixed-amplitude-output, no-modulation, modest-stability generator may be just the ticket. For someone else (or perhaps for you) you might want tight frequency control, exceptionally low phase noise and the ability to run signal levels up and down between -100dBm and +20dBm. Someone else may want versatile modulation.

The (digital sampling) waveform generators I've seen aren't capable of the low spurious output levels and ease of adjusting modulation that I see in things typically called signal generators, and generally not of accurate output level control over a wide range. On the other hand, typical signal generators can't produce arbitrary waveforms (or essentially arbitrary spectra).

Cheers,
Tom

So when after the five time constants the voltage is across the capacitor
is about 99 volts and the current has decayed to less than a milliamp the
"flow of energy" into the capacitor is higher then at time zero?

signals.

OK, then suppose we illuminate an antenna with a CW EM wave, then
connect a receiver to detect it. Are you CERTAIN that no other
EM fields can possibly interfere with this process, yet do so
entirely by linear effects?

OK, what if I use a second distant transmitter with
identical frequency? I bet I can create an RF interference
pattern so that the above receiving antenna is in an antinode,
and the received power drops essentially to zero. I've done
it with wave-superposition, which obviously is totally linear.
This stuff with "energy sucking antennas" uses the same
process: it uses the superposition of fields of the SAME
FREQUENCY as the incoming waves. The waves and the antenna's
field are coherent. If you say that one AC field cannot alter
under any circumstances, then maybe you've never encountered
interference patterns.

Because the AC fields originated by the electrically-short
antennas have the same frequency as the incoming waves,
odd things occur which would not occur if the two
frequencies differed. In particular, if the short antenna
surrounds itself with a non-radiating local field which
partially CANCELS OUT the fields of an incoming EM wave,
then nothing nonlinear has occurred. Yet energy has gone
missing from space. The cancelled energy ends up within
the short antenna. Plots of the Poynting vector field show
that the cancellation process deflects the incoming waves so
that they flow into the tiny antenna. Their energy appears
in whatever load is connected.

I've said it several times now but it bears repeating:
"ENERGY SUCKING" ANTENNAS WORK BY TOTALLY CONVENTIONAL

PRINCIPLES. They're only "weird" because they aren't
commonly discussed or analyzed. And, since the same
basic principles apply to half-wave dipoles, the concept
is not weird in the least. It's just "different drummer"
thinking. We normally assume that a half-wave dipole is
purely an absorber, and we usually ignore the fact that all
antenns creates their own local field. It's this local
field which grabs the EM waves out of the air.

> That immediately tells me that the response to some signal we wish to
> receive will not be changed by some other field around, or current in,
> or voltage across the feedpoint of, our antenna.

If you are discussing DC fields, or fields which have
a different frequency than the incoming waves, then you are
right. But as soon as the "other field" has the same frequency
as the incoming waves, then that field gains the ability to
reinforce or to cancel those waves. Earlier I was talking
about synchronous motors as an analogy for "energy
sucking" antennas. I didn't think I had to point out
that synchronous PM motors are SYNCHRONOUS, and that their
rotor-magnets turn at the same frequency as the drive fields.

wonder what is acceptable limit of grid current in a 2x 6146B
amplifier?
ALC voltage is often derived from varying grid current over bias
network resistors, usually around 10k resistance. 1mA grid current
will develop 10V voltage drop.

Coupled via a 0.002uF capacitor to a voltage doubling rectifier with
output loaded by 0.1uF (ALC circuit) will maximum give -0.2V
A feasable voltage, the ALC circuit may not have any real function at
all
I modified the FL-dx-500 and received very good reports for improving
readability, but it still seems that few mA grid current is within
acceptable limit of grid current for this sort of amplifier using 2x
6JS6A or 6146B

I think that jan-martin is recommending a stub, but I'm not sure. If you take a 1/4 wavelength long
piece of coax, and keep one end open circuit, the other end will appear to be a short circuit.
So you can simply "Tee" the stub into your antenna transmission line. However, the Q might be low enough to
degrade the wanted signal that is 26 MHz lower.

Waveform generators usually go from a few HZ to about 20 mhz or less,they have sine, square,rect,sawtooth etc.output varing up to about 20 Volts peak to peak ..the sig generator usually has sine wave output and can have AM modulation,FM mod,etc. frequency usually starts in low KHZ and may go into GHZ range ,they have a calibrated attenuator in the output and output can be set from a tenth of a microvolt to maybe 1 volt.RMS. Dave asks -
> Apart from a load of bent wire what do I need?
==========
An enquiring, perhaps suspicious mind.

Before picking up your hammer, ask yourself what great benefits, if any, do you expect to accrue over and above those available from an ordinary beam constructed of the same number of elements. It is essential to think in numerical/quantitative terms, such as relative forward gain, front-to-back ratio, radiating efficiency and bandwidth.

Do you intend to write a paper on the subject ? Best to leave that decision until after you have completed the field and anechoic-chamber measurements.

BTW, have you considered investigating the crossed-field antenna. (CFA).

This is EXACTLY the kind of crank message from a few hams that has produced and fueled one of ham radio's major flame subjects, and one of the worst chapters in it's history, resulting in its apex of: 1) fraudulent, racist hoaxing by a ham that never even saw a fractal antenna; 2) death and harmful intent threats caste upon a professional, academic antenna designer by an errant radio amateur; 3) virulent rumors of fraud, and reason for suspicion against an expert in the antenna field.

Reg--

You suggest reasons for being suspicious. OK, let's bite. In fact, take off a BIG chunk. Go the the original references on fractal antenna articles--and there are now about 100 of them in professional and amateur journals and magazines alike--and give the good people on this NG some basis for being suspicious.

I should like to inform those on this NG the 'Reg' has been a profound antagonist on this subject--ignoring information and data if he felt that it did not feed into his objective: to produce and fan a flame and injure the reputation of me.

The relevant question--so posed by my colleague at RPI--stands: what is the basis for the flame war. Looking at Reg, you see the answer.

Objectively, scientifically, there is no basis for flame other than to attack someone who merely tried to help.

The gain in dB is 10 * log base 10 (Pout/Pin.)
Or vica versa,
Solve for linear: Gain= 10^ (dB/10)

dB to linear: 10^(22/10)= 158.5

linear to dB: 10 * log 158.5 = 22 dB.

So if 1 mW of power was at the amplifier's input, the output would have 158.5 mW.
0 dBm 22.0 dBm.

I am planning a new amp and noticed that most of the newer designs do not use inductive chokes in the high voltage supply. Back when I learned about such things a filter choke was considered essential for good hum filtering with variable (keyed) loads..... What's the story? Should I use a choke or go with the newer design (and cheaper) and use only caps????

Try using a CAD program or a spreadsheet to plot the energy
flow into a capacitor versus time (when powered by a
100Vdc supply with a 100K resistor.)

The curve starts at zero, ramps up smoothly, comes to
a maximum, then falls back to zero as the current falls.
(The peak power is when the V/I of the capacitor is
100K ohms, which gives an impedance match for
an instant.)

When the Vc is much smaller than Vsupply, and if the
power supply has constant impedance, the energy
absorbed by the capacitor per second depends on the
voltage across the capacitor. If you wished to force the
capacitor to suddenly start absorbing more energy, you
could use another power supply to goose the Vc higher.

This is an analogy for the "energy-sucking antenna",
where a large e-field produced by the antenna can
cause it to receive more signal power from the incoming
EM waves. As with the capacitor, the LC resonant
antenna will create stronger local fields as its stored
energy ramps up, and this increases the absorbed
power, but since this is a 2-dimensional situation
(rather than the 1-D of the capacitor), I think

it means that the received power will rise exponentially
whenever an EM wavetrain first hits the tiny antenna-
resonator.

Chokes cost money and weigh alot. When dealing with RF only, it is just cheaper to go with a bigger filter capacitor. It is doubtful that you will pick up any noticable hum on the RF if the filter is any size at all. That is big enough to keep the voltage from sagging too low from no load to full load current.

I cannot see how you can compare the DC transient conditions of a simple RC circuit with the AC dynamics of an resonant circuit. Antennas cannot store energy.

I'm certain that fields (photons) can only be altered due to the
mediation of charged matter. Other fields alone cannot alter them.

> under any circumstances, then maybe you've never encountered
> interference patterns.

Interference patterns are simple superposition. The Principle of
Superposition says that the components of a superposition are
unaltered by the superposition. Beyond the superposition zone
we still have the same two waves, still with the same directions
and the same energies as they had before the superposition
occurred.

> Because the AC fields originated by the electrically-short
> antennas have the same frequency as the incoming waves,
> odd things occur which would not occur if the two

> missing from space. The cancelled energy ends up within
> the short antenna. Plots of the Poynting vector field show
> that the cancellation process deflects the incoming waves so
> that they flow into the tiny antenna. Their energy appears
> in whatever load is connected.

The energy has *not* "gone missing". That is a misunderstanding
of what has happened. The E fields are vectors, and add vectrorially
at the point of superposition. So if their relative phase is 180 degrees
we have

(+E) + (-E) = 0

But that doesn't mean that energy has gone to zero. Energy
is proprortional to the *square* of E

(+E)^2 + (-E)^2

Squaring E (dot product) yields a positive scalar.
We can write this another way

|P| + |P| = 2P

That holds for any relative phase. Thus energy at the point of
interference is twice that of either component of the superposition
alone. This is always true. No energy goes missing, nor does energy
suddenly appear if the E field vectors happen to be in phase rather
than out of phase.

Diagramatically, if we have two beams of energy 1 that
cross, the situation looks like this

1 1
2
1 1

Now the E vectors may look like this if they're in phase opposition

1 -1
0
-1 1

or they might look like this if they are coincident in phase

1 1
2
1 1

But energy never goes missing. Energy is always a positive
scalar quantity, not a vector.

> the difference in signal strength.

This opinion shows up frequently, but not everyone agrees. If you're running sufficient power and conditions are good, it's certainly true. A 6 dB change (from a bit less than one to as many as 3 S-units, depending on what rig you have) won't be noticeable -- the AGC takes up the slack. But when you're operating near the noise level, 6 dB easily makes the difference between solid copy and no copy at all. This is particularly true on the lower frequency bands (40, 80, 160), where there's more noise.

Anyone who thinks 6 dB makes no difference is a fool to buy a beam. After all, the gain of a 3-element beam is about 6 dB relative to a dipole.

> the same? Wish to swap experiences/ideas/knowledge of pens.. ink resist
etc.

I have a friend who used a "B" sized Roland DXY-1100 flat bed pen plotter. There was just enough room for a 0.064 inch PCB copper clad board to fit under the pen when it was in the up position. The ink pen used was one of those "disposable" black ink oil based pens with a felt tip (0.3mm size). These pens are used to plot on overhead transparencies. The ink resists the Ferric Chloride just fine. When the tip starts to wear out, just throw it out and use a new one out of the sealed bag they come in. These pens were fairly cheap.

When he was done with the copper side he just flipped the board over and plotted the "silk-screen" on the component side of the board.

For double sided boards you can either use a double sided copper clad board (0.064 inch) or use two separate single sided copper clad boards (0.031 inch). For the dual board method drill two pilot holes in each board (on opposite corners if you can) just big enough for a stick pin to fit through it. Use a spray adhesive on the non-copper side of each board and align the two boards using the stick pins. Then carefully press the two boards together. All that's left is to drill the through holes for components and solder wires in the via's to connect the top and bottom traces together.

1692. Need ideas

Newsgroup: rec.radio.amateur.homebrew
Date: 2000-03-06 00:00:00 UTC
From: "Clifton T. Sharp Jr." <clifto@clifto.com>
Message-ID: <38C48756.76E811F4@clifto.com>
Source record: 62746

What I really need is a DC-to-light spectrum analyzer, but since I'm many dollars away from that I'm going to have to come up with some alternative. I'd like ideas for homebrewing some sort of gizmos to start detecting whatever man-made, NON-QRN interference appears to be around here.

Weird things are happening all over the house, but mostly in the shack-cum-computer-room.

1. GE 900 MHz *spread-spectrum* cordless phone. Ordinarily, it works great; goes a full block easily. At odd times, for periods of one to three hours, something appears to be interfering with it so badly that it needs to be within six inches of the base unit to function; three feet away and it suffers lots of segments of "dead air", i.e. chopping in and out.

2. LG digital cell phone. Works wonderfully everywhere, except at odd times and around the house, especially in the shack. Suddenly for periods of one to three hours, signal strength is nearly nothing, operation is terrible.

3. Ten days ago I bought on clearance a Radio Shack "atomic" clock that sets itself by WWVB. According to its manual it checks the time several times each day. Tonight for the first time it was blinking an indicator that says it had not been able to set itself for the past 48 hours. TEN SECONDS in another part of the house (literally the time it took to walk to the kitchen) was enough to reset it. The unit and its antenna were in the same exact spot for the ten days in which I've owned it. AM reception on my FRG-7, three feet from the clock, shows no QRN-type interference, but all AM stations have a peculiar sound defect similar to what you'd get from a dirty potentiometer; all controls are fine (if there's one thing I *can* do, 33 years after I started working in TV service, it's to clean controls and switches).

4. (Probably incidental; included for completeness.) DSL was installed here January 27. The provider has been able to go to a full megabit for other installations as far as 12,000 line-feet from the DSLAM; I am measured at 4700 feet and can only get 784K. Provider cites strange noise on the lines and expresses surprise that they can't go any faster on that short a line.

5. No CBers in the area; nearest ham is five blocks away and has been for nine years with no problems. Closest likely RF source is a land mobile tower two blocks from here; again, it's been two blocks from me for nine years. Nothing heard through FRG-7, televisions, VCR, stereos (component and handheld), speakers or computer audio. Nothing seems out of the ordinary on the BC700A scanner, but it has enough images to make it nearly useless as a detection tool. Old, cheap diode-and-d'arsonval FSM shows nothing. There are numerous cell towers within a mile, no new ones in the last two

years.

6. There are long periods of impulse QRN in this general area from various sources at various times. There seems to be no relation between that and the problem described above, as there is not always impulse QRN detectable during these times (handheld AM radio used as detector).

Agreed. I understand the point about working at the noise level. I think the
money and effort would be better spent on reducing feedline losses and
putting up a gain antenna. What's the point of spending money on an
amplifier to burn up 3db, or more, in the feedline/ATU connected to a dipole
hanging from a tree outside and they can hear his signal but he can't hear
theirs?

At least reducing feedline losses and putting up a gain antenna works both
ways. A real worth while exercise if one is working at the noise floor of
the receiver.

never mind, and certainly not class C linear amp (as suggested above),
but the original questions still is:

wonder what is acceptable limit of grid current in a 2x 6146B
amplifier?
ALC voltage is often derived from varying grid current over bias
network resistors, usually around 10k resistance. 1mA grid current
will develop 10V voltage drop.

Coupled via a 0.002uF capacitor to a voltage doubling rectifier with
output loaded by 0.1uF (ALC circuit) will maximum give -0.2V
A feasable voltage, the ALC circuit may not have any real function at
all
I modified the FL-dx-500 and received very good reports for improving
readability, but it still seems that few mA grid current is within
acceptable limit of grid current for this sort of amplifier using 2x
6JS6A or 6146B

Seems that for 1000W linears fraction of 1mA grid current is too much
to avoid splatter, so an exciter with 1mA grid current isn't well for
the guy 10kHz up or down....

there are 2 kinds of choke, the swinging kind and the resonant kind. Henry Radio uses the resonant kind. If your AMP is QRO plus use a a resonant choke supply the peak current from your mains is less. This enables you too run a super big tube without to much investment in heavy copper drop leads to your shack. Besides getting high capacity oil capacitors that are true filter caps are both expensive and hard to find, the string of brand new electrolytics are no cheaper. But again we dont know what your voltage and current needs are. If your amp is not table top i would use a resonat choke supply, you can buy a matched choke capacitor pair from Peter Dahl. I built the mother of all power supplies running a resonat choke supply and i can run any tube from 2 8877s to a 4cx10000, the money invested was worth it. I installed it in the roof and i run heavy 50 KV 20 amp wire to amp. I can run all 9 bands at about 2 kw from this single supply. You could never do that with a capacitor filter power supply. Most military amps and broadcast transmitter are running resonant choke supplies

Then going to 100 watts on SSB will only result in a 6 db increase, 1 "S"
unit. Its not worth the effort or the money. Almost nobody will even notice
the difference in signal strength.

I've probably missed 95% of the postings on this thread.

If I take a transmitter far away and near by I have a
spherical volume and two cases:
1. the volume is empty
2. the volume contains a load and a dipole cut to
the frequency of the far away transmitter

I then compute the surface integral of the Poynting
vector over those spherical surfaces I will find
that in case 1, no power is absorbed and in case 2,
some power is absorbed. I will also find that
the em fields on those two surfaces are different
and I will find that the differences are entirely
attributable to the motions of charges in the load
and dipole. This is all true. A similar situation
exists regarding the secondary of an ordinary transformer.

Its the "more" in the quoted paragraph that I question.

Opinions expressed herein are my own and may not represent those of my employer.

Curtis,

Doug, W1FB, wrote a similar article for the Dec 1994 CQ magazine. It shows
how to construct a transmitter in stages. At the completion of each stage
you have a working transmitter. Subsequent stages add function. One stage
adds a 3 x 2N2222 rf amp. He says they boost the power to 1 watt.

Very true, but the big difference with the antenna is that it's a two way
street, the gain applies to both transmit as well as receive. IMHO, this is
much more beneficial than just adding a few more watts ...

Leland, with all due respect, I have to disagree. Anyone who works
weak-signal DX will tell you that 6db is often the difference between
qso and no qso. Hams spend hundreds of dollars for antennas which
give them a few db more, and for good reason. True, when the signal
is 20 over 9, then 6db is not noticeable, but not when it's in the
noise.

> >> > flow into the capacitor.

Have you tried plotting this curve? I ask because you
seem to be attacking what I say, and if you actually try
messing with a simulation of this triviall circuit ,
you'll instantly answer these questions.

It's not a contradiction: when the capacitor's voltage
is very small, the capacitor's incoming energy-flow
grows linearly, and also its voltage grows linearly. When
the voltage BECOMES LARGE RELATIVE TO THE POWER SUPPLY
VOLTAGE, this no longer holds true.

In the analogy with the electrically-short resonant
antenna, things work in similar fashion: the rising
antenna voltage can only act to "draw in" extra energy
when the field strength at a quarter-wavelength away
from the antenna is very small when compared to the
amplitude of the incoming EM waves. The incoming EM
waves are analogous to the power supply which drives
the capacitor above. When the voltage on the resonant
antenna grows very large, it stops "drawing in" extra
energy-flow in proportion to voltage.

> > (The peak power is when the V/I of the capacitor is
> > 100K ohms, which gives an impedance match for
> > an instant.)
>
> Impedance match? Of what to what?

Instantaneous impedance match, not just impedance match.
The instantaneous impedance match of the capacitor's V/I
at one instant, to the 100K resistor that's in series with
the power supply. In other words, as the V and I in the
capacitor are changing, at one instant the capacitor's V
divided by the I will be 100,000. That's also the instant
when the rate of energy flowing into the capacitor is
maximum. If we imagine a capacitor to be like a resistor

which changes its resistance over time, then when the
capacitor's "resistance" is 100K, the capacitor is absorbing
energy at a maximum rate.

>
> I cannot see how you can compare the DC transient conditions of a
simple RC
> circuit with the AC dynamics of an resonant circuit.

I was using this capacitor-analogy because an earlier posting
claimed (though not in these exact words) that there was no
situation where the fields associated with an electronic
component could affect the energy flowing into that component.
Capacitors do it. But this is only an analogy, not a proof
that resonant small antennas do the same. The whole point
of an analogy is an aid to understanding, and is not a proof.
How can I compare the two? BY ANALOGY! The capacitor is
sort of like a "low frequency case" of the way fields can
alter energy flow.

> Antennas cannot store
> energy.

ANTENNAS CANNOT STORE ENERGY????? Please recall that we
are discussing LC circuits which are being used as antennas.
That's what I mean when I say "small resonant antenna".
LC circuits don't store energy?

The critical part is that the antennas I'm discussing
are electrically short, and are connected to a tank
circuit which is tuned to resonance with the incoming
waves.

Agreed.

> Its the "more" in the quoted paragraph that I question.

Yes, that's the key question: does connecting a tank
circuit to a short dipole (or small loop) cause it to
absorb MORE energy from the incoming waves? More
specifically, if we connect just a resistive load to
a short dipole and adjust that resistor for maximum
received power, can we receive even MORE power if we
then connect a lossless tank circuit across that dipole,
then re-adjust that resistor value for maximum power?
These papers imply that the answer is yes:

C. F. Bohren, "How can a particle absorb more than the light incident on it?", Am J Phys, 51 #4, pp323 Apr 1983

H. Paul and R. Fischer "Light Absorbtion by a dipole", SOV. PHYS. USP.,
26(10) Oct. 1983 pp 923-926

These papers look at the absorbtion of em waves by electrically small particles (both metal particles and dielectric.) They show that whenever there is a resonator onboard a particle, it creates a very strong local field, and since this field is synchronized to the incoming em waves, it distorts them in such a way as to make them deflect towards the particle. The particle ends up absorbing more energy than if the resonator was not present. In other words, the "effective area" of a small particle becomes enlarged when there is a resonator present.

Very strange, no? The upshot: a 1-angstrom atom can easily absorb 6000-angstrom red light waves if that atom behaves as an LC resonant antenna at that frequency. I had previously imagined that tiny atoms absorb long light waves because the light is "really" photons. This turns out to be wrong. From a wave-oriented viewpoint, atoms can absorb energy of huge wavelength because an atom is like a tank circuit, and it can generate an intense AC field in its nearfield region.

Also, it explains why the loopstick in an AM radio works so well. That loopstick has a tuning capacitor, and if this "energy sucking" effect is real, then the effective area of the tiny loopstick antenna becomes much larger when it's tuned to resonance.

I'd always assumed that the capacitor on an AM radio loopstick was only there to form a bandpass circuit which rejects off-freq stations. Imagine my suprise when I read those two physics papers above. They imply that AM loopstick antennas contain some very interesting physics. Just imagine: we can vary the electrical size of a small antenna by altering the circuitry to which it connects. It's as if the tiny antenna can throw up a "virtual lens" made out of vibrating EM fields. Is any of this stuff useful? Who knows! At least for me it's a new toy for my brain to futz with.

Complex issue it is and we were stupid to get involved. It's in
Europe's back yard and it's time for them to start paying for their
own defense. They've been dependent upon us since WWII. They've
fully recovered now, so it's time for them to start paying their own
way both in money and lives. Excellent article at:

Chip, is that you? There is a web wire supplier at www.wiretron.com.
You could also use bare 12ga with some space between the windings.
Nah, you are using ~200 feet. How about insulated wire from Home
Depot/Lowes? Will the insulation matter that much? If so, try
wiretron.

You'd probably be better off scrapping the supplies and considering another option for producing the 15 volts you need. Or, the other option would be to install a motor-generator (alternator) set, with the alternator portion having a three phase output to drive the supplies (Or, for that matter, have the alternator supply 10.6 volts at three phase, and rectify and filter that.).

Or, you might be able to increase the filter capacitor size by a couple of orders of magnitude (Yes, a couple of orders of magnitude, not a couple of times.).

The problem is that a three phase full wave rectifier produces a very smooth output. With a three phase power source, there are three waves, each offset by 120 degrees from each other. The full wave rectifier effectively changes this to six waves each offset by 60 degrees from each other. Thus, the output from the rectifier is composed of the 60 degrees from each wave where it's the maximum. This is 30 degrees either side of the peak. Thus, the output from the rectifier starts at .866 (Cosine(30)=.866) times the peak line voltage, goes up to the peak line voltage, and then drops back down to 866 the peak line voltage. At this point, the next diode in the rectifier starts conducting for the next wave, and the process repeats. Thus, the output from the rectifier fluctuates between .866 times the peak and the peak line voltage. Therefore, there's very little filtration that needs to be performed by a capacitor.

Now, if you consider the case of a single phase full wave rectifier, the output starts at zero, goes to the peak line voltage, and then back to zero, at which time the other diode starts conducting and the process repeats. However, because the voltage swings are much deeper (all the way down to zero), and because the voltage pulses are farther apart (180 degrees, rather than 60 degrees), the capacitor used to filter the output must be significantly larger. After all, the capacitor has to supply the entire energy for the switching power supply while the input voltage is below the level necessary to run the switcher.

The net results is that a three phase, full-wave power supply needs almost no filtering by capacitors, while a single phase power supply needs extensive filtering.

It might be possible to feed single phase power into the power supply, but you would have to significantly increase the size of the filter capacitor bank. You'd then have to worry about things like surge current limits on the diodes, and if a single diode (diode pair?) would be rated for the worst case current consumption by the supply (In the three phase case, each diode only conducts for a much smaller portion of the cycle.).

So, the net result is that while you might be able to get them to work if you throw enough knowledge and capacitors at them, it may be simpler to build a supply for what you need rather than converting them.

If you do decide to persue your approach, then remember that your supply has to supply a LOT of current at 150 volts. The power out from the switching supply is 15V*150A=2250W. If you assume 100 percent efficiency (which we all know can't be achieved), the current required from the input would be 2250W/150V=15.4A. Thus, if you factor in a resonable efficiency, and account for startup surges, peaks, etc., you'll probably need to supply somewhere around 20-30 amps at 150 volts.

Dave

Here is a source of some confusion. The individual fields are unaltered,
but you only measure them through the effect that the SUM has on your
instrument...

>
>(+E) + (-E) = 0
>
>But that doesn't mean that energy has gone to zero. Energy

You have to get the same result that you got by adding the fields
and then squaring the total. You get the result by remebering
that your square is an inner product. For a phase which isn't
constant in time, the inner product is 0.

There's the technique of ironing on the graphic design from regular laser or copy machine paper. Make sure your board is clean, then with a warm to medium heat, (the type of iron used to iron clothes) firmly press from the non-ink side of the paper onto the board. I've used this method to transfer graphics onto painted surfaces as well.

A short dipole presents a mainly capacitive (plus some
resistance) impedance to its load. So in case 1,
I get to optimize only the source resistance, and
in case 2 I get to optimize the source resistance
and throw in a parallel R and C?

It look like a no brainer. Case 2. If the
source is capacitive, let the load be inductive.

I'd look at it from a load matching point of view.

It might be easier to understand with a series L
rather than a shunt L. I think this is the same
concept as base loading the antenna.

Opinions expressed herein are my own and may not represent those of my employer.

> I'm certain that fields (photons) can only be altered due to the
> mediation of charged matter. Other fields alone cannot alter them.

Then we're in agreement, I think. When a normal 1/2-wave
dipole antenna absorbs energy from incoming EM waves, it
is the charged matter within the metal which causes the
antenna to grab energy from the EM waves. However,
pointlike particles don't magically interact with EM
waves, instead it is their surrounding fields which
perform the trick. Regardless of the type of antenna,
it is the LOCAL FIELDS associated with the charges
which interact with the EM waves and cause the energy
to eventually wind up flowing along the antenna's
lead-in cable.

That's why I keep saying that the FIELDS of the electrically
short antenna are reaching out and grabbing EM waves. The
fields of the electrically short antennas are created by
the motions of charged matter within those antennas. By
superposing with the fields of the incoming EM waves,
the antenna's local fields cause enery to be diverted from
the wave. I certainly agree that fields alone
(meaning propagating EM waves far from any matter) cannot
affect other propagating waves in this fashion.

> Interference patterns are simple superposition. The Principle of
> Superposition says that the components of a superposition are
> *unaltered* by the superposition. Beyond the superposition zone
> we still have the same two waves, still with the same directions
> and the same energies as they had before the superposition
> occurred.

True for propagating waves, but not true for the fields in
the nearfield zone of a piece of charged matter such as an
antenna. When a half-wave dipole generates a local field,
the end result is that some of the energy in the incoming
EM waves is intercepted by the antenna. Superposition

still holds true, yet that half-wave dipole was able
to punch a hole in the wavetrain of EM waves passing by.
Do you object to this? If not, then why are electrically
small resonant antennas (with their huge local fields)
such a problem?

I think you might want to review your concepts, since
the idea that "fields allow antennas to intercept EM
waves" applies to all antennas, not just to these
weird resonant antennas.

And make no mistake, the charges are required as
well. You cannot create a dipole field without charges,
and it is the oscillating dipole field and its associated
charges in the conductors which performs the absorbtion
process in both a 1/2-wave dipole and in a tiny resonant
antenna.

> > In particular, if the short antenna

> > that the cancellation process deflects the incoming waves so
> > that they flow into the tiny antenna. Their energy appears
> > in whatever load is connected.
>
> The energy has *not* "gone missing".

Gone missing FROM SPACE, from the travelling EM wave. The
energy is now inside the load resistor connected to the
antenna. This is true of a half-wave dipole, and just as
true of a tiny resonant antenna.

> That is a misunderstanding of what has happened.

I think not. I think I'm unable to get my ideas across
clearly. Also it might be because I'm coming from an
unconventional viewpoint; thinking in terms of the
local fields generated by an antenna rather than in terms
of current through it or voltage across it. I hadn't
realized this was unconventional, but people here are
attacking some concepts which I didn't think were
controversial or even open to debate.

If you are certain that a normal half-wave dipole can
intercept EM waves without the dipole generating fields
of its own, then we have a serious problem. If you
accept the existence of these local fields generated by
the antenna, but are certain that they play no role in
the interception of the energy from the EM waves, then we

have a serious problem. You're no longer arguing about
the tiny antennas, but instead have begun questioning
antenna-physics itself.

Check out the "Simple CMOS Keyer" in the ARRL Handbook. I built one back in the early 90's, worked great. I am not sure if it is still in the handbook, but it was in the 1990 and 1993 handbooks.

Good luck.

Hello group..want to show a few pictures of what i am stripping out of these old radar chassis.Got about 20 of these down my dads basement. 1950's.. BC-1268?(forget the correct number at the moment) radar control consoles.Bunch of oil capacitors, http://www.ezaccess.net/moz/DCP00681.jpg And the thing here that is kind of a mystery, http://www.ezaccess.net/moz/DCP00682.jpg Has markings on it that read,THE MUTTER CO., TYPE 433-AC, OHMS 10,000, and the counter has VEEDER-ROOT INC. HARTFORD CONN. Seems was some kind of giant rehostat, and it is geared down pretty good. The front was marked range control. Think i might be able to use this for some type of receive antenna tuner project? Thanks..Bob

>
> 73 Robin G3LBA

Hello--
I recall seeing a thread on this topic some time ago-- for best results, one would need
a waterproof ink that wets copper but withstands resist. The only flavor of plotter-pen
ink I could locate contained toxic ingredients and was no longer sold in the U.S. Shortly
after, we visited Toronto, and I called a bunch of graphics-supply houses, only to find
that no one in Canada sold the ink, either. Maybe it's availabe in the U.K.?

Problem 2: attaching the PC board to the plotter-- one might try double-sided stick tape
and a sheet of thick, rough-surfaced carrier paper. A fixed-bed plotter might work best.

One might also contemplate using a subtractive method: flood the raw PC board with
an acid-resistant compound (perhaps "bluing" as sold in gun shops?; Or coating the board
with soft wax?) and using a sharp stylus in the penholder to scrape away the resist
where one doesn't want copper to remain. The wax-removal method would need a vacuum-cleaner pickup to remove the wax shavings.

You might try a search on www.deja.com on the topic, and please do keep the NG posted as to your findings.

> at VHF.

Hello--
In case anyone needs a quantity of similat transistors, I have the following
devices
available:

TN-2219A National Semiconductor NPN general-purpose NPN transistor:
100 < hFE < 300 at Ic= 150 mA; BVcbo = 75 V min.; BVceo = 40 V min.;
Icbo = 10 nA max. at Vcb= 60 V; Cob = 8 pf max.; Ft = 60 MHz min.
at Ic = 20 mA. NF 4 dB (max.)

In TO-237 metal-tabbed plastic package (similar to TO-92); this package
reduces thermal resistance from 125 C per watt for a TO-92 to 50 C per watt for
the TO-237.
Not bad for building a QRP rig for the low bands around a single device!
$1.00 for 20 pieces; $5.00 for 120 pieces

Contact me for postage, or more information.

73,
Brad AA1IP

We have had little luck using this technique and would appreciate some tips! The first problem is finding a plotter which will accept 2mm PCB. A Roland XY plotter was the best in the end but the ink would bead instead of coating the copper. For now it is back to the photographic (wasteful) technique but a working recipe would be welcomed.

Cheers,

Sounds like a normal switch mode PSU but connected to
230 instead of 110vac. The line volts here are 240vac
and that is rectified to go across the 2 stacked
capacitors. You don't state the capacity of the caps.

Inside most of them is a jumper or switch so that
the recifiers can act as a doubler for 110-120vac
The voltage across the phases is not 120v on a house
supply in the US. It's more like 230v

At 150A the transistors must be pretty lumpish and the
ferrite transformers, too!

There have been some articles around lately about
using PC supplies for 14v output but at a much more modest
20A - 40A.

The ones you have sound as if they would make a great
starting place for a shack supply.

As a matter of terminology, it is usually said
that there is one field, but if convenient, it
can be decomposed into terms attributed to charges
and currents at a far away source and other
terms that are attributed to charges and currents
in the nearby antenna. But I also use the short
hand terminology of talking about these separate
terms as separate fields.

Anyway, it is certain that the total field with the
antenna is different from the total field
without the antenna.

> That's why I keep saying that the FIELDS of the electrically
> short antenna are reaching out and grabbing EM waves.

I think I'd say that the currents and charge distributions
in the antenna distort the field from what it would be
if the antenna were not there.

> antenna.

I'd say it was true for independent waves. But what is
different here is that the field component from the antenna
currents is dependent on the component from the far away
sources. Another way of looking at it is simply that
the field with the antenna is different from the field
without the antenna.

> When a half-wave dipole generates a local field,

> Do you object to this?

My objection is one of emphasis. The way you have told it,
it sounds to me like you consider the source fields and the
antenna field to be two separate fields. I would say there
are two fields: one for the case with the antenna and one for
the case without (sounding now somewhat like a broken
record).

> If not, then why are electrically
> small resonant antennas (with their huge local fields)

> controversial or even open to debate.

I think its just the way you tell it.

I think you could even apply your view to dc circuits.
The load allows currents to flow which change the fields
from what they would be if there were no currents. And if
there were no currents, Poynting's vector integrated over
the surface of the load would be zero.

Sure. I see it in terms of mental models. Having a variety
of mental models gives us a "larger toolkit". If we see
the field as a single entity, some interesting ideas
unfortunately vanish. My hobby is to look for unorthodox
viewpoints in hopes of gaining insights I lacked before.
But since the ideas aren't in all the textbooks, I don't
trust them entirely, and I put them here so others might
find any obvious holes which I've missed.

With these antennas, I've been thinking in terms of three
viewpoints: incoming EM waves without the antenna fields,
antenna-generated fields without the incoming EM waves,
and also the superposition.

Which leads me to wonder: don't halfwave dipoles also
generate their own fields? If the field being generated
by a tiny resonant antenna is the reason that the antenna
can absorb EM waves, maybe the same idea applies to ALL
antennas.

> > That's why I keep saying that the FIELDS of the electrically
> > short antenna are reaching out and grabbing EM waves.
>
> I think I'd say that the currents and charge distributions
> in the antenna distort the field from what it would be
> if the antenna were not there.

OK, but it is not obvious that a current alone can "draw in"
the energy of an EM wave. Thinking in terms of the field
produced by that antenna current helps explain what's going
on. It takes some of the mystery out of the "nearfield"
stuff. The Bohren paper has a diagram where the dipolar
e-field of a tiny antenna is added to the e-field of

incoming plane EM waves, and when the Poynting vector is
plotted (it's perpendicular to the distorted field lines)
it proves to deflect inwards and dive into the tiny antenna.
Very weird.

> I'd say it was true for independent waves. But what is
> different here is that the field component from the antenna
> currents is dependent on the component from the far away
> sources.

Not totally true in the case of the resonant antenna. Yes,
the stored energy in the resonator did originally come from
the incoming EM waves. However, it built up over many
cycles. If the incoming wavetrain was to suddenly come
to an end, then the oscillating fields produced by the
small antenna's LC circuit would continue. (The antenna
is too small to radiate much energy.) The antenna's
fields are not created by the incoming EM waves, instant
by instant, and it is conceivable that they could be
created by a power supply with the goal of increasing the
antenna's effective size, as Sutton and Spaniol did in
their active ELF antenna (papers referenced at the end
of http://www.amasci.com/tesla/tesceive.html)

> My objection is one of emphasis. The way you have told it,
> it sounds to me like you consider the source fields and the
> antenna field to be two separate fields.

But they are, and in the same way that the fields of
two bar magnets are "separate" whether the bar magnets
are adjacent or very distant. It's also true that the
EM waves will permanently alter the fields of the small
antenna, but it takes many cycles for this to occur.

If we suddenly remove the incoming EM waves, yet the
antenna's fields persist, then I think I have reason to
assert that the antenna's fields are an independant entity
(which of course can superpose with any other field which
happens to appear.) And if we have two bar magnets, we
usually think in terms of two dipole fields which are
superposed, rather than thinking in terms of a single
more complicated field which cannot be decomposed into
something simpler.

> I would say there
> are two fields: one for the case with the antenna and one for
> the case without (sounding now somewhat like a broken
> record).

Heh. And a third: the case where there are no incoming
EM plane waves, but the LC circuit in the tiny antenna is
still oscillating and producing a local field surrounding

the antenna.

>
> > If not, then why are electrically
> > small resonant antennas (with their huge local fields)
> > such a problem?
>
> I missed something. What problem?

My previous reply was to Mr. Coffman, who insisted that
an AC EM field could not deflect the Pointing vector of an
EM wave (and therefore I am wrong about the ability of
these tiny antennas to deflect EM energy into themselves.)

>

>
> I think its just the way you tell it.

Right! I'm speaking in clear terms, yet they are
unconventional, so everyone seems to have objections.
Yet there is nothing wrong with my terminology, except
that it is non-traditional. My goal is to see if others
can find a hole in my arguments, and to make myself
think. Unfortunately, this tends to force others to
think as well, and I suspect that many people don't
enjoy that one bit! :) Of course I'm getting a bit
of an advantage, since I've been beating my head on these
ideas for awhile, rather than having them suddenly dumped
into my lap by some weirdo on the newsgroups.

> I think you could even apply your view to dc circuits.
> The load allows currents to flow which change the fields
> from what they would be if there were no currents. And if
> there were no currents, Poynting's vector integrated over
> the surface of the load would be zero.

Yeah! And circuits connect with antennas in the realm of
AC motors. A coil can drive a rotating permanent magnet.
If the magnet bearings have friction, the magnet is essentially
"sucking energy" from the drive coil, and integrating the
Poynting vector over a spherical surface surrounding only the
magnet would show energy flowing inwards. That same magnet
can be driven by radio waves (if the frequency is very low
or the RPM of the magnet is very high.) In that situation,

EM energy is absorbed by the rotating magnet and it ends up as heat in the bearings. This is a very unorthodox "radio antenna", no? If the magnet size is << wavelength, then it is very similar to these electrically small resonant antennas. If the magnet is made very strong, then it couples more strongly to the incoming EM waves, and can extract a larger energy flow. And if the EM field generated by the resonator builds up to a high amplitude, that antenna "acts larger" than it actually is.
